

Forth 200x Standardisation Committee

**Forth 200x Draft 17.1**

7<sup>th</sup> September, 2017

**Notice: Status of this Document**

This is a draft proposed Standard to replace ~~ANSI X3.215-1994~~ the Forth 2012 standard . As such, this is not a completed standard. The Forth 200x Standardisation Committee may modify this document during the course of its work.

## Foreword

Forth is a language for direct communication between human beings and machines. Forth was invented by Charles Moore to increase programmer productivity without sacrificing machine efficiency. Using natural-language diction and machine-oriented syntax, Forth provides an economical, productive environment for interactive compilation and execution of programs. Forth also provides low-level access to computer-controlled hardware, and the ability to extend the language itself. This extensibility allows the language to be quickly expanded and adapted to special needs and different hardware systems. Forth provides for highly interactive program development and testing.

In the interests of transportability of application software written in Forth, standardization efforts began in the mid-1970s by an international group of users and implementors who adopted the name “Forth Standards Team”. This effort resulted in the Forth-77 Standard. As the language continued to evolve, an interim Forth-78 Standard was published by the Forth Standards Team. Following Forth Standards Team meetings in 1979, the Forth-79 Standard was published in 1980. Major changes were made by the Forth Standards Team in the Forth-83 Standard, which was published in 1983. The ANS Forth Standard was published in 1994<sup>1</sup> and was adopted as an international standard in 1997<sup>2</sup>.

x:reset

~~The ANS Forth committee was formed in 1987 to address the fragmentation within the Forth community caused not only by the difference between Forth 79 and Forth 83 but the exploitation of technical developments. Undertaking a comprehensive review of existing implementations they moved away from prescribing stringent requirements, preferring to describe the operation of the virtual machine, without reference to an implementation. The ANS Forth Standard was published in 1994<sup>1</sup> and was adopted as an international standard in 1997<sup>2</sup>.~~

~~Changes are proposed and discussed in the electronic media: the usenet news group `comp.lang.forth`; the `forth200x@yahoogroups.com` email list; the `www.forth200x.org` web site. Annual public meeting are held to review and vote on the proposed changes.~~

The Forth 200x Standardisation Committee was formed in 2004 to allow the Forth community to contribute to an updated standard. Their work led to the Forth-2012 Standard<sup>3</sup>.

The Forth Standards Committee has taken over this work. Changes are proposed and discussed on the [forth200x@yahoogroups.com](mailto:forth200x@yahoogroups.com) email list and the [www.forth-standard.org](http://www.forth-standard.org) web site. Annual public meetings are held to review and vote on the proposed changes. This document is the result of the public review these meetings first held on October 21–22, 2005 (Santander) and subsequently on September 14–15, 2006 (Cambridge), September 13–14, 2007 (Dagstuhl), September 25–26, 2008 (Vienna), March 25–27, 2009 (Neuenkirchen, Rheine), September 2–4, 2009 (Exeter), March 24–26, 2010 (Rostock), September 22–24, 2010 (Hamburg), September 21–23, 2011 (Vienna), September 12–14, 2012 (Oxford), September 25–27, 2013 (Hamburg), September 24–26, 2014 (Palma de Mallorca), September 30–October 2, 2015 (Bath) and subsequently on 7–9 September, 2016 (Konstanz).

## Proposals Process

In developing a standard it is necessary for the standards committee to know what the system implementors and the programmers are already doing in that area, and what they would be willing to do, or wish for.

To that end we have introduced a system of consultation with the Forth community:

- a) A proponent of an extension or change to the standard writes a proposal.
- b) The proponent publishes the proposal as an *RfD* (Request for Discussion) by sending a copy to the `forth200x@yahoogroups.com` email list *and* to the `comp.lang.forth` usenet news group where it can be discussed. The maintainers of the `www.forth200x.org` web site will then place a copy of the proposal on that web site.

Be warned, this will generate a lot of heated discussion.

In order for the results to be available in time for a standards meeting, an RfD should be published at least 12 weeks before the next meeting.

If a proposal does not propose extensions or changes to the Forth language, but a rewording of the current document, there is nothing for a system implementor to implement, or a programmer to use. In such a case, the proposal should be published as a Request for Comment (RfC). The proposal will be considered, along with any comments, at the next committee meeting.

- c) The proponent can modify the proposal, taking any comments into consideration. Where comments have been dismissed, both the comment and the reasons for its dismissal should be given. The revised proposal is published as a revised RfD/RfC.
- d) Once a proposal has settled down, it is frozen, and submitted to a vote taker, who then publishes a *CfV* (Call for Votes) on the proposal. The vote taker will normally be a member of the standards committee. In the poll, system implementors can state, whether their systems implement the proposal, or what the chances are that it ever will. Similarly, programmers can state whether they have used something similar to the proposed extension and whether they would use the proposed extension once it is standardized. The results of this poll are used by the standards committee when deciding whether to accept the proposal into the standards document.

In order for the results to be available in time for a standards meeting, the CfV should be started at least 6 weeks before that meeting.

- e) One to two weeks after publishing the CfV, the vote taker will publish a *Current Standings*. Note that the poll will remain open, especially for information on additional systems, and the results will be updated on the Forth200x web page. The results considered at a standards meeting are those from four weeks prior to that meeting. If no poll results are available by that deadline, the proposal will be considered at a later meeting.
- f) A proposal will only be accepted into the new basis document by consensus of those present at a standards meeting. If you can not attend a meeting, you should ask somebody who is attending to champion the proposal on your behalf.

Should a contributor consider their comments to have been dismissed without due consideration, they are encouraged to submit a counter proposal.

Proposals which have passed the poll will be integrated into the basis document in preparation for the approaching standards committee meeting. Proposals often require some rewording in this process, so the proponent should work with the editor to integrate the proposal into the document.

A proposal should give a rationale for the proposal, so that system implementors and programmers may see the relevance of the proposal and why they should adopt (and vote for) it. The proposal should include the following sections, where appropriate.

**Author:**

The name of the author(s) of the proposal.

**Change Log:**

A list of changes to the last published edition on the proposal.

**Problem:**

This states what problem the proposal addresses.

**Solution:**

An informal description of the proposed solution to the problem identified by the proposal.

**Typical use:**

Shows a typical use of the word/feature you propose; this should make the formal wording easier to understand.

**Remarks:**

This gives the rationale for specific decisions you have taken in the proposal (often in response to comments in the RfD phase), or discusses specific issues that have not been decided yet.

**Proposal:**

This is the formal or normative part of the proposal and should be as well specified as possible.

Some issues could be left undecided in the initial RfDs, leaving the issue open for discussion. These issues should be mentioned in the Remarks section as well as in the Proposal section.

If you want to leave something open to the system implementor, make that explicit, e.g., by making it an ambiguous condition.

For the wording of word definitions, it is normally a good idea to take your inspiration from existing word definitions in the basis document. Where possible you should include the rationale for the definition. Should a proposal be accepted where no rationale has been provided, the editor will construct a rationale from other parts of the proposal. The proponent should work with the editor in the development of this rationale.

**Reference implementation:**

This makes it easier for system implementors to adopt your proposal. Where possible they should be provided in standard Forth, as defined by this document. Where this is not possible, system specific knowledge is required or non standard words are used, this should be documented.

**Testing:**

This should test the feature/words you propose, in particular, it should test boundary conditions. Where possible test cases should be written to conform with John Hayes `tester.f` test harness, see Appendix F.

**Experience:**

Indicate where the proposal has already been implemented and/or used.

**Comments:**

Initially this is blank. As comments are made on the proposal, they should be incorporated into the proposal. Comment which can not be incorporated should be included in this section. A response to the comment may be included after the comment itself.

**Instructions for responding to the poll:**

Once the proposal enters the CfV stage, the vote taker will add these instructions to the proposal.

## 200x Membership

This document is maintained by the Forth 200x Standards Committee. The committee meetings are open to the public, anybody is allowed to attend a physical meeting as an observer.

Committee membership is open to anybody who can attend physical meetings. On attending a physical meeting, a non-member becomes an observer. An observer becomes a voting member by attending the next physical meeting. An observer will not normally be allowed to vote except at the discretion of the committee. A member will be deemed to have resigned from the committee by failing to attend two consecutive physical meetings.

Electronic meetings of the committee are held between physical meetings as required.

Currently the committee has the following voting members:

<u>Prof. Sergey Baranov</u> .....	<u>SPIIRAS</u>	ed17
<u>snbaranov@googlemail.com</u>	<u>St. Petersburg, Russia</u>	
<u>Willem Botha</u> .....	Construction Computer Software (Pty) Ltd	
<u>willem.botha@ccssa.com</u>	Cape Town, South Africa	
<u>Dr. M. Anton Ertl (Chair)</u> .....	Technische Universität Wien	
<u>anton@mips.complang.tuwien.at</u>	Wien, Austria	
<u>Andrew Haley</u> .....	<u>Red Hat UK Ltd.</u>	
<u>aph@redhat.com</u>	<u>Cambridge, UK</u>	
<u>Dr. Ulrich Hoffmann</u> .....	FH Wedel	
<u>uho@forth-ev.de</u>	Wedel, Germany	
<del><u>Simon Kaphahn</u></del> .....	<del>Independent Member</del>	
<del><u>Simon_K99@gmx.de</u></del>	<del>Munich, Germany</del>	
<u>Dr. Peter Knaggs (Editor)</u> .....	Independent Member	
<u>pjk@bcs.org.uk</u>	Trowbridge, UK	
<u>Bernd Paysan (Treasure)</u> .....	Net2o	
<u>bernd.paysan@gmx.de</u>	Munich, Germany	
<u>Stephen Pelc (Chair)</u> .....	MicroProcessor Engineering Ltd.	
<u>stephen@mpfeforth.com</u>	Southampton, UK	
<u>Leon Wagner</u> .....	FORTH, Inc.	
<u>leon@forth.com</u>	Los Angeles, USA	
<u>Gerald Wodni (Technical)</u> .....	Independent Member	
<u>gerald@wodni.at</u>	Wien, Austria	

The following organizations and individuals have also participated in this project as committee members. The committee recognizes and respects their contributions:

<u>Federico de Ceballos</u> .....	Universidad de Cantabria
<u>federico.cebaldos@unican.es</u>	Santander, Spain

Andrew Haley .....	aph@redhat.com	Red Hat UK Ltd. Cambridge, UK
<u>Simon Kaphahn</u> .....	<u>Simon_K99@gmx.de</u>	<u>Independent Member</u> <u>Munich, Germany</u>
Dr. Bill Stoddart .....	w.j.stoddart@gmail.com	Teesside University Middlesbrough, UK
Dr. Willi Stricker .....	stricker_w@t-online.de	Independent Member Springe, Germany
Carsten Strotmann .....	carsten@strotmann.de	Independent Member Neuenkirchen, Germany

The committee would like to thank the following contributors:

John Hayes	Bruce McFarling	Howerd Oakford
Marcel Hendrix	Charles G. Montgomery	Tim Partridge
Gerry Jackson	Krishna Myneni	Elizabeth Rather
Alex McDonald		David N. Williams

## Forth 2012 200x Standard

# 1 Introduction

## 1.1 Purpose

The purpose of this standard is to promote the portability of Forth programs for use on a wide variety of computing systems, to facilitate the communication of programs, programming techniques, and ideas among Forth programmers, and to serve as a basis for the future evolution of the Forth language.

## 1.2 Scope

This standard specifies an interface between a Forth System and a Forth Program by defining the words provided by a Standard System.

### 1.2.1 Inclusions

This standard specifies:

- the forms that a program written in the Forth language may take;
- the rules for interpreting the meaning of a program and its data.

### 1.2.2 Exclusions

This standard does not specify:

- the mechanism by which programs are transformed for use on computing systems;
- the operations required for setup and control of the use of programs on computing systems;
- the method of transcription of programs or their input or output data to or from a storage medium;
- the program and Forth system behavior when the rules of this standard fail to establish an interpretation;
- the size or complexity of a program and its data that will exceed the capacity of any specific computing system or the capability of a particular Forth system;
- the physical properties of input/output records, files, and units;
- the physical properties and implementation of storage.

## 1.3 Document organization

### 1.3.1 Word sets

This standard groups Forth words and capabilities into *word sets* under a name indicating some shared aspect, typically their common functional area. Each word set may have an extension, containing words that offer additional functionality. These words are not required in an implementation of the word set.

The “Core” word set, defined in sections 1 through 6, contains the required words and capabilities of a Standard System. The other word sets, defined in sections 7 through 18, are optional, making it possible to provide Standard Systems with tailored levels of functionality.

#### 1.3.1.1 Text sections

Within each word set, section 1 contains introductory and explanatory material and section 2 introduces terms and notation used throughout the standard. There are no requirements in these sections.

Sections 3 and 4 contain the usage and documentation requirements, respectively, for Standard Systems and Programs, while section 5 specifies their labeling.

Sections  $x.1$ – $x.6$  of each word set have the same section numbering as sections 1–6 of the whole document to make it easy to relate the sections to each other. This may lead to gaps in section numbers if a particular section does not occur in a word set.

#### 1.3.1.2 Glossary sections

Section 6 of each word set specifies the required behavior of the definitions in the word set and the extensions word set.

### 1.3.2 Annexes

The annexes do not contain any required material.

Annex A provides some of the rationale behind the committee’s decisions in creating this standard, as well as implementation examples. It has the same section numbering as the body of the standard to make it easy to relate each requirements section to its rationale section.

Annex B is a short bibliography on Forth.

Annex C discusses the compatibility of this standard with earlier Forths.

Annex D presents some techniques for writing portable programs.

Annex F presents a test suite to test the operation of a system complies with the definitions documented in this standard.

Annex H is an index of all Forth words defined in this standard.

## 1.4 Future directions

### 1.4.1 New technology

This standard adopts certain words and practices that are increasingly found in common practice. New words have also been adopted to ease creation of portable programs.

### 1.4.2 Obsolescent features

This standard adopts certain words and practices that cause some previously used words and practices to become obsolescent. Although retained here because of their widespread use, their use in new implementations or new programs is discouraged, as they may be withdrawn from future revisions of the standard.

This standard designates the following word as obsolescent:

15.6.2.1580 **FORGET**  
6.2.2530 **[COMPILE]**  
13.6.2.1795 **LOCALS |**

This standard designates the following practice as obsolescent:

- Using **ENVIRONMENT?** to enquire whether a word set is present.

## 2 Terms, notation, and references

The phrase “See:” is used throughout this standard to direct the reader to other sections of the standard that have a direct bearing on the current section.

In this standard, “shall” states a requirement on a system or program; conversely, “shall not” is a prohibition; “need not” means “is not required to”; “should” describes a recommendation of the standard; and “may”, depending on context, means “is allowed to” or “might happen”.

Throughout the standard, typefaces are used in the following manner:

- This proportional serif typeface is used for text, with *italic* used for symbols and the first appearance of new terms;
- A bold proportional sans-serif typeface is used for **headings**;
- A bold monospaced serif typeface is used for Forth-language **text**.

### 2.1 Definitions of terms

Terms defined in this section are used generally throughout this standard. Additional terms specific to individual word sets are defined in those word sets. Other terms are defined at their first appearance, indicated by italic type. Terms not defined in this standard are to be construed according to the *Dictionary for Information Systems*, ANSI X3.172-1990.

**address unit:** Depending on context, either 1) the units into which a Forth address space is divided for the purposes of locating data objects such as characters and variables; 2) the physical memory storage elements corresponding to those units; 3) the contents of such a memory storage element; or 4) the units in which the length of a region of memory is expressed.

**aligned:** Divisible by a type-dependent power of 2 (typically used as “*<type>*-aligned address” or “*<type>*-aligned value”).

**aligned address:** The address of a memory location at which a character, cell, cell pair, or double-cell integer can be accessed.

**ambiguous condition:** A circumstance for which this standard does not prescribe a specific behavior. See section [4.1.2 Ambiguous conditions](#) for a list of such circumstances and [3.4.4 Possible actions on an ambiguous condition](#).

**cell:** The primary unit of information in the architecture of a Forth system.

**cell pair:** Two cells that are treated as a single unit.

**character:** Depending on context, either 1) a storage unit capable of holding a character; or 2) a member of a character set.

**character-aligned address:** The address of a memory location at which a character can be accessed.

**character string:** Data space that is associated with a sequence of consecutive character-aligned addresses. Character strings usually contain text. Unless otherwise indicated, the term “string” means “character string”.

- code space:** The logical area of the dictionary in which word semantics are implemented.
- compile:** To transform source code into dictionary definitions.
- compilation semantics:** The behavior of a Forth definition when its name is encountered by the text interpreter in compilation state.
- counted string:** A data structure consisting of one character containing a length followed by zero or more contiguous data characters. Normally, counted strings contain text.
- cross compiler:** A system that compiles a program for later execution in an environment that may be physically and logically different from the compiling environment. In a cross compiler, the term “host” applies to the compiling environment, and the term “target” applies to the run-time environment.
- current definition:** The definition whose compilation has been started but not yet ended.
- data field:** The data space associated with a word defined via [CREATE](#).
- data space:** The logical area of the dictionary that can be accessed.
- data-space pointer:** The address of the next available data space location, i.e., the value returned by [HERE](#).
- data stack:** A stack that may be used for passing parameters between definitions. When there is no possibility of confusion, the data stack is referred to as “the stack”. Contrast with **return stack**.
- data type:** An identifier for the set of values that a data object may have.
- defining word:** A Forth word that creates a new definition when executed.
- definition:** A Forth execution procedure compiled into the dictionary.
- dictionary:** An extensible structure that contains definitions and associated data space.
- display:** To send one or more characters to the user output device.
- environmental dependencies:** A program’s implicit assumptions about a Forth system’s implementation options or underlying hardware. For example, a program that assumes a cell size greater than 16 bits is said to have an environmental dependency.
- execution semantics:** The behavior of a Forth definition when it is executed.
- execution token:** A value that identifies the execution semantics of a definition.
- find:** To search the dictionary for a definition name matching a given string.
- immediate word:** A Forth word whose compilation semantics are to perform its execution semantics.
- implementation defined:** Denotes system behaviors or features that must be provided and documented by a system but whose further details are not prescribed by this standard.
- implementation dependent:** Denotes system behaviors or features that must be provided by a system but whose further details are not prescribed by this standard.
- initiation semantics:** Describes the behavior at the start of some word definitions (those of words defined with `:`, `:NONAME`, `CREATE DOES>`). Other parts of the specification of these defining words (and nothing else) refer to initiation semantics.

**input buffer:** A region of memory containing the sequence of characters from the input source that is currently accessible to a program.

**input source:** The device, file, block, or other entity that supplies characters to refill the input buffer.

**input source specification:** A set of information describing a particular state of the input source, input buffer, and parse area. This information is sufficient, when saved and restored properly, to enable the nesting of parsing operations on the same or different input sources.

**interpretation semantics:** The behavior of a Forth definition when its name is encountered by the text interpreter in interpretation state.

**keyboard event:** A value received by the system denoting a user action at the user input device. The term “keyboard” in this document does not exclude other types of user input devices.

**line:** A sequence of characters followed by an actual or implied line terminator.

**name space:** The logical area of the dictionary in which definition names are stored.

**number:** In this standard, “number” used without other qualification means “integer”. Similarly, “double number” means “double-cell integer”.

**parse:** To select and exclude a character string from the parse area using a specified set of delimiting characters, called delimiters.

**parse area:** The portion of the input buffer that has not yet been parsed, and is thus available to the system for subsequent processing by the text interpreter and other parsing operations.

**pictured-numeric output:** A number display format in which the number is converted using Forth words that resemble a symbolic “picture” of the desired output.

**program:** A complete specification of execution to achieve a specific function (application task) expressed in Forth source code form.

**receive:** To obtain characters from the user input device.

**return stack:** A stack that may be used for program execution nesting, do-loop execution, temporary storage, and other purposes.

**standard word:** A named Forth procedure, formally specified in this standard.

**user input device:** The input device currently selected as the source of received data, typically a keyboard.

**user output device:** The output device currently selected as the destination of display data.

**variable:** A named region of data space located and accessed by its memory address.

**word:** Depending on context, either 1) the name of a Forth definition; or 2) a parsed sequence of non-space characters, which could be the name of a Forth definition.

**word list:** A list of associated Forth definition names that may be examined during a dictionary search.

**word set:** A set of Forth definitions grouped together in this standard under a name indicating some shared aspect, typically their common functional area.

## 2.2 Notation

### 2.2.1 Numeric notation

Unless otherwise stated, all references to numbers apply to signed single-cell integers. The inclusive range of values is shown as *{from ... to}*. The allowable range for the contents of an address is shown in double braces, particularly for the contents of variables, e.g., **BASE** *{{2 ... 36}}*.

### 2.2.2 Stack notation

Stack parameters input to and output from a definition are described using the notation:

( *stack-id*: *before* -- *after* )

where *stack-id* specifies which stack is being described, *before* represents the stack-parameter data types before execution of the definition and *after* represents them after execution. The symbols used in *before* and *after* are shown in table 3.1.

The control-flow-stack *stack-id* is “C:”, the data-stack *stack-id* is “S:”, and the return-stack *stack-id* is “R:”. When there is no confusion, the data-stack *stack-id* may be omitted.

When there are alternate *after* representations, they are described by “*after*<sub>1</sub> | *after*<sub>2</sub>”. The top of the stack is to the right. Only those stack items required for or provided by execution of the definition are shown.

### 2.2.3 Parsed-text notation

If, in addition to using stack parameters, a definition parses text, that text is specified by an abbreviation from table 2.1, shown surrounded by double-quotes and placed between the *before* parameters and the “--” separator in the first stack described, e.g.,

( S: *before* “*parsed-text-abbreviation*” -- *after* )

Table 2.1: Parsed text abbreviations

Abbreviation	Description
<i>&lt;char&gt;</i>	the delimiting character marking the end of the string being parsed
<i>&lt;chars&gt;</i>	zero or more consecutive occurrences of the character <i>&lt;char&gt;</i>
<i>&lt;space&gt;</i>	a delimiting space character
<i>&lt;spaces&gt;</i>	zero or more consecutive occurrences of the character <i>&lt;space&gt;</i>
<i>&lt;quote&gt;</i>	a delimiting double quote
<i>&lt;paren&gt;</i>	a delimiting right parenthesis
<i>&lt;eol&gt;</i>	an implied delimiter marking the end of a line
<i>ccc</i>	a parsed sequence of arbitrary characters, excluding the delimiter character
<i>name</i>	a token delimited by space, equivalent to <i>ccc&lt;space&gt;</i> or <i>ccc&lt;eol&gt;</i>

### 2.2.4 Glossary notation

The glossary entries for each word set are listed in the standard ASCII collating sequence. Each glossary entry specifies a Forth word and consists of two parts: an *index line* and the *semantic description* of the definition.

### 2.2.4.1 Glossary index line

The index line is a single-line entry containing, from left to right:

- Section number, the last four digits of which assign a unique sequential number to all words included in this standard;
- **DEFINITION-NAME** in upper-case, mono-spaced, bold-face letters;
- Natural-language pronunciation in quotes if it differs from English;
- Word-set designator from table 2.2. The designation for extensions word sets includes “EXT”.
- Extension designator in sans-serif font under the Word-set designator for words which have been added to the standard via the named extension.

Table 2.2: Word set designators

Word set	Designator
Core word set	CORE
Block word set	BLOCK
Double-Number word set	DOUBLE
Exception word set	EXCEPTION
Facility word set	FACILITY
File-Access word set	FILE
Floating-Point word set	FLOATING
Locals word set	LOCALS
Memory-Allocation word set	MEMORY
Programming-Tools word set	TOOLS
Search-Order word set	SEARCH
String-Handling word set	STRING
Extended-Character word set	XCHAR

### 2.2.4.2 Glossary semantic description

The first paragraph of the semantic description contains a stack notation for each stack affected by execution of the word. The remaining paragraphs contain a text description of the semantics. See [3.4.3 Semantics](#).

### 2.2.5 BNF notation

The following notation is used to define the syntax of some elements within the document:

- Each component of the element is defined with a rule consisting of the name of the component (italicized in angle-brackets, e.g., *<decdigit>*), the characters := and a concatenation of tokens and metacharacters;
- Tokens may be literal characters (in bold face, e.g., **E**) or rule names in angle brackets (e.g., *<decdigit>*);
- The metacharacter \* is used to specify zero or more occurrences of the preceding token (e.g., *<decdigit>\**);

- Tokens enclosed with [ and ] are optional (e.g., [-]);
- Vertical bars separate choices from a list of tokens enclosed with braces (e.g., { 0 | 1 }).

See: [3.4.1.3 Text interpreter input number conversion](#), [12.3.7 Text interpreter input number conversion](#), [12.6.1.0558 >FLOAT](#), [12.6.2.1613 FS .](#), [13.6.2.2550 { :.](#)

## 2.3 References

The following national and international standards are referenced in this standard:

- ISO/IEC 15145:1997 *Information technology. Programming languages. FORTH*;
- ANSI X3.215-1994 *Programming Languages – Forth*;
- ANSI X3.172-1990 *Dictionary for Information Systems*, ([2.1 Definitions of terms](#));
- ANSI X3.4-1974 *American Standard Code for Information Interchange (ASCII)*, ([3.1.2.1 Graphic characters](#));
- ISO 646-1983 *ISO 7-bit coded character set for information interchange, International Reference Version (IRV)* ([3.1.2.1 Graphic characters](#));
- ANSI/IEEE 754-1985 *Floating-point Standard*, ([12.2.1 Definition of terms](#)).

## 3 Usage requirements

A system shall provide all of the words defined in [6.1 Core words](#). It may also provide any words defined in the optional word sets and extensions word sets. No standard word provided by a system shall alter the system state in a way that changes the effect of execution of any other standard word except as provided in this standard. A system may contain non-standard extensions, provided that they are consistent with the requirements of this standard.

The implementation of a system may use words and techniques outside the scope of this standard.

A system need not provide all words in executable form. The implementation may provide definitions, including definitions of words in the Core word set, in source form only. If so, the mechanism for adding the definitions to the dictionary is implementation defined.

A program that requires a system to provide words or techniques not defined in this standard has an environmental dependency.

### 3.1 Data types

A data type identifies the set of permissible values for a data object. It is not a property of a particular storage location or position on a stack. Moving a data object shall not affect its type.

No data-type checking is required of a system. An ambiguous condition exists if an incorrectly typed data object is encountered.

Table [3.1](#) summarizes the data types used throughout this standard. Multiple instances of the same type in the description of a definition are suffixed with a sequence digit subscript to distinguish them.

#### 3.1.1 Data-type relationships

Some of the data types are subtypes of other data types. A data type  $i$  is a subtype of type  $j$  if and only if the members of  $i$  are a subset of the members of  $j$ . The following list represents the subtype relationships using the phrase “ $i \Rightarrow j$ ” to denote “ $i$  is a subtype of  $j$ ”. The subtype relationship is transitive; if  $i \Rightarrow j$  and  $j \Rightarrow k$  then  $i \Rightarrow k$ :

```
+n ⇒ u ⇒ x;
+n ⇒ n ⇒ x;
char ⇒ +n;
a-addr ⇒ c-addr ⇒ addr ⇒ u;
flag ⇒ x;
xt ⇒ x;
ior ⇒ n ⇒ x;
+d ⇒ d ⇒ xd;
+d ⇒ ud ⇒ xd.
```

Any Forth definition that accepts an argument of type  $i$  shall also accept an argument that is a subtype of  $i$ .

Table 3.1: Data types

<i>Symbol</i>	<i>Data type</i>	<i>Size on stack</i>
<i>flag</i>	flag	1 cell
<i>true</i>	true flag	1 cell
<i>false</i>	false flag	1 cell
<i>char</i>	character	1 cell
<i>n</i>	signed number	1 cell
<i>+n</i>	non-negative number	1 cell
<i>u</i>	unsigned number	1 cell
<i>u   n</i> <sup>1</sup>	number	1 cell
<i>x</i>	unspecified cell	1 cell
<i>xt</i>	execution token	1 cell
<i>addr</i>	address	1 cell
<i>a-addr</i>	aligned address	1 cell
<i>c-addr</i>	character-aligned address	1 cell
<i>ior</i>	error result	1 cell
<i>d</i>	double-cell signed number	2 cells
<i>+d</i>	double-cell non-negative number	2 cells
<i>ud</i>	double-cell unsigned number	2 cells
<i>d   ud</i> <sup>2</sup>	double-cell number	2 cells
<i>xd</i>	unspecified cell pair	2 cells
<i>colon-sys</i>	definition compilation	implementation dependent
<i>do-sys</i>	do-loop structures	implementation dependent
<i>case-sys</i>	<b>CASE</b> structures	implementation dependent
<i>of-sys</i>	<b>OF</b> structures	implementation dependent
<i>orig</i>	control-flow origins	implementation dependent
<i>dest</i>	control-flow destinations	implementation dependent
<i>loop-sys</i>	loop-control parameters	implementation dependent
<i>nest-sys</i>	definition cells	implementation dependent
<i>i * x, j * x, k * x</i> <sup>3</sup>	any data type	0 or more cells

<sup>1</sup> May be either a signed number or an unsigned number depending on context.

<sup>2</sup> May be either a double-cell signed number or a double-cell unsigned number depending on context.

<sup>3</sup> May be an undetermined number of stack entries of unspecified type. For examples of use, see [6.1.1370 EXECUTE](#), [6.1.2050 QUIT](#).

### 3.1.2 Character types

Characters shall have the following properties:

- be at least one address unit wide;
- be exactly one address unit wide;
- contain at least eight bits;
- be of fixed width;
- have a size less than or equal to cell size;

x:1 chars = 1

- be unsigned.

The characters provided by a system shall include the graphic characters {32 ... 126}, which represent graphic forms as shown in table 3.2.

### 3.1.2.1 Graphic characters

A graphic character is one that is normally displayed (e.g., A, #, &, 6). These values and graphics, shown in table 3.2, are taken directly from ANS X3.4-1974 (ASCII) and ISO 646-1983, International Reference Version (IRV). The graphic forms of characters outside the hex range {20 ... 7E} are implementation defined. Programs that use the graphic hex 24 (the currency sign) have an environmental dependency.

The graphic representation of characters is not restricted to particular type fonts or styles. The graphics here are examples.

Table 3.2: Standard graphic characters

Hex IRV ASCII	Hex IRV ASCII	Hex IRV ASCII	Hex IRV ASCII	Hex IRV ASCII	Hex IRV ASCII
20	30 0 0	40 @ @	50 P P	60 ` `	70 p p
21 ! !	31 1 1	41 A A	51 Q Q	61 a a	71 q q
22 " "	32 2 2	42 B B	52 R R	62 b b	72 r r
23 # #	33 3 3	43 C C	53 S S	63 c c	73 s s
24 ♂ \$	34 4 4	44 D D	54 T T	63 d d	74 t t
25 % %	35 5 5	45 E E	55 U U	64 e e	75 u u
26 & &	36 6 6	46 F F	56 V V	65 f f	76 v v
27 ' '	37 7 7	47 G G	57 W W	66 g g	77 w w
28 ( (	38 8 8	48 H H	58 X X	67 h h	78 x x
29 ) )	39 9 9	49 I I	59 Y Y	68 i i	79 y y
2A * *	3A : :	4A J J	5A Z Z	69 j j	7A z z
2B + +	3B ; ;	4B K K	5B [ [	6A k k	7B { {
2C , ,	3C < <	4C L L	5C \ \	6C l l	7C
2D - -	3D = =	4D M M	5D ] ]	6D m m	7D } }
2E . .	3E > >	4E N N	5E ^ ^	6E n n	7E ~ ~
2F / /	3F ? ?	4F O O	5F _ _	6F o o	

### 3.1.2.2 Control characters

All non-graphic characters included in the implementation-defined character set are defined in this standard as control characters. In particular, the characters {0 ... 31}, which could be included in the implementation-defined character set, are control characters.

Programs that require the ability to send or receive control characters have an environmental dependency.

### 3.1.2.3 Primitive Character

A primitive character (pchar) is a character with no restrictions on its contents. Unless otherwise stated, a “character” refers to a primitive character.

### 3.1.3 Single-cell types

The implementation-defined fixed size of a cell is specified in address units and the corresponding number of bits. See [D.2 Hardware peculiarities](#).

Cells shall be at least one address unit wide and contain at least sixteen bits. The size of a cell shall be an integral multiple of the size of a character. Data-stack elements, return-stack elements, addresses, execution tokens, flags, and integers are one cell wide.

#### 3.1.3.1 Flags

Flags may have one of two logical states, *true* or *false*. A true flag returned by a standard word shall be a single-cell value with all bits set. A false flag returned by a standard word shall be a single-cell value with all bits clear.

#### 3.1.3.2 Integers

The implementation-defined range of signed integers shall include  $\{-32768 \dots +32767\}$ . The implementation-defined range of non-negative integers shall include  $\{0 \dots 32767\}$ . The implementation-defined range of unsigned integers shall include  $\{0 \dots 65535\}$ .

#### 3.1.3.3 Addresses

An address identifies a location in data space with a size of one address unit, which a program may fetch from or store into except for the restrictions established in this standard. The size of an address unit is specified in bits. Each distinct address value identifies exactly one such storage element. See [3.3.3 Data space](#).

The set of character-aligned addresses, addresses at which a character can be accessed, is an implementation-defined subset of all addresses. Adding the size of a character to a character-aligned address shall produce another character-aligned address.

The set of aligned addresses is an implementation-defined subset of character-aligned addresses. Adding the size of a cell to an aligned address shall produce another aligned address.

#### 3.1.3.4 Counted strings

A counted string in memory is identified by the address (*c-addr*) of its length character.

The length character of a counted string shall contain a binary representation of the number of data characters, between zero and the implementation-defined maximum length for a counted string. The maximum length of a counted string shall be at least 255.

#### 3.1.3.5 Execution tokens

Different definitions may have the same execution token if the definitions are equivalent.

#### 3.1.3.6 Error results

A value of zero indicates that the operation completed successfully; other values are in the range  $\{-4095 \dots -1\}$  and represent a valid [THROW](#) code.

The meanings of values in the range  $\{-255 \dots -1\}$  are defined by table [9.1 THROW code assignments](#). Values in the range  $\{-4095 \dots -256\}$  and their meanings are implementation defined.

A word that returns an *ior* will not **THROW** that *ior* as an exception, but indicates the exception through the *ior*. This allows a program to take appropriate actions, which may include throwing the exception.

### 3.1.4 Cell-pair types

A cell pair in memory consists of a sequence of two contiguous cells. The cell at the lower address is the first cell, and its address is used to identify the cell pair. Unless otherwise specified, a cell pair on a stack consists of the first cell immediately above the second cell.

#### 3.1.4.1 Double-cell integers

On the stack, the cell containing the most significant part of a double-cell integer shall be above the cell containing the least significant part.

The implementation-defined range of double-cell signed integers shall include  $\{-2147483647 \dots +2147483647\}$ .

The implementation-defined range of double-cell non-negative integers shall include  $\{0 \dots 2147483647\}$ .

The implementation-defined range of double-cell unsigned integers shall include  $\{0 \dots 4294967295\}$ . Placing the single-cell integer zero on the stack above a single-cell unsigned integer produces a double-cell unsigned integer with the same value. See [3.2.1.1 Internal number representation](#).

#### 3.1.4.2 Character strings

A string is specified by a cell pair (*c-addr u*) representing its starting address and length in characters.

### 3.1.5 System types

The system data types specify permitted word combinations during compilation and execution.

#### 3.1.5.1 System-compilation types

These data types denote zero or more items on the control-flow stack (see [3.2.3.2](#)). The possible presence of such items on the data stack means that any items already there shall be unavailable to a program until the control-flow-stack items are consumed.

The implementation-dependent data generated upon beginning to compile a definition and consumed at its close is represented by the symbol *colon-sys* throughout this standard.

The implementation-dependent data generated upon beginning to compile a do-loop structure such as **DO** ... **LOOP** and consumed at its close is represented by the symbol *do-sys* throughout this standard.

The implementation-dependent data generated upon beginning to compile a **CASE** ... **ENDCASE** structure and consumed at its close is represented by the symbol *case-sys* throughout this standard.

The implementation-dependent data generated upon beginning to compile an **OF** ... **ENDOF** structure and consumed at its close is represented by the symbol *of-sys* throughout this standard.

The implementation-dependent data generated and consumed by executing the other standard control-flow words is represented by the symbols *orig* and *dest* throughout this standard.

### 3.1.5.2 System-execution types

These data types denote zero or more items on the return stack. Their possible presence means that any items already on the return stack shall be unavailable to a program until the system-execution items are consumed.

The implementation-dependent data generated upon beginning to execute a definition and consumed upon exiting it is represented by the symbol *nest-sys* throughout this standard.

The implementation-dependent loop-control parameters used to control the execution of do-loops are represented by the symbol *loop-sys* throughout this standard. Loop-control parameters shall be available inside the do-loop for words that use or change these parameters, words such as **I**, **J**, **LEAVE** and **UNLOOP**.

## 3.2 The implementation environment

### 3.2.1 Numbers

#### 3.2.1.1 Internal number representation

This standard requires ~~two's-complement~~ two's-complement number representation and arithmetic. Arithmetic zero is represented as the value of a single cell with all bits clear. x:2-complement

The representation of a number as a compiled literal or in memory is implementation dependent.

#### 3.2.1.2 Digit conversion

Numbers shall be represented externally by using characters from the standard character set. Conversion between the internal and external forms of a digit shall behave as follows:

The value in **BASE** is the radix for number conversion. A digit has a value ranging from zero to one less than the contents of **BASE**. The digit with the value zero corresponds to the character "0". This representation of digits proceeds through the character set to the decimal value nine corresponding to the character "9". For digits beginning with the decimal value ten the graphic characters beginning with the character "A" are used. This correspondence continues up to and including the digit with the decimal value thirty-five which is represented by the character "Z". The characters "a" through "z" should be treated the same as "A" through "Z", with "a" having the value ten and "z" the value thirty-five. The conversion of digits outside this range is implementation defined.

#### 3.2.1.3 Free-field number display

Free-field number display uses the characters described in digit conversion, without leading zeros, in a field the exact size of the converted string plus a trailing space. If a number is zero, the least significant digit is not considered a leading zero. If the number is negative, a leading minus sign is displayed.

Number display may use the pictured numeric output string buffer to hold partially converted strings (see [3.3.3.6 Other transient regions](#)).

## 3.2.2 Arithmetic

### 3.2.2.1 Integer division

Division produces a quotient  $q$  and a remainder  $r$  by dividing operand  $a$  by operand  $b$ . Division operations return  $q$ ,  $r$ , or both. The identity  $b \times q + r = a$  shall hold for all  $a$  and  $b$ .

When unsigned integers are divided and the remainder is not zero,  $q$  is the largest integer less than the true quotient.

When signed integers are divided, the remainder is not zero, and  $a$  and  $b$  have the same sign,  $q$  is the largest integer less than the true quotient. If only one operand is negative, whether  $q$  is rounded toward negative infinity (floored division) or rounded towards zero (symmetric division) is implementation defined.

Floored division is integer division in which the remainder carries the sign of the divisor or is zero, and the quotient is rounded to its arithmetic floor. Symmetric division is integer division in which the remainder carries the sign of the dividend or is zero and the quotient is the mathematical quotient “rounded towards zero” or “truncated”. Examples of each are shown in tables 3.3 and 3.4.

In cases where the operands differ in sign and the rounding direction matters, a program shall either include code generating the desired form of division, not relying on the implementation-defined default result, or have an environmental dependency on the desired rounding direction.

Table 3.3: Floored Division Example				Table 3.4: Symmetric Division Example			
Dividend	Divisor	Remainder	Quotient	Dividend	Divisor	Remainder	Quotient
10	7	3	1	10	7	3	1
-10	7	4	-2	-10	7	-3	-1
10	-7	-4	-2	10	-7	3	-1
-10	-7	-3	1	-10	-7	-3	1

### 3.2.2.2 Other integer operations

x:2-complement

In all integer arithmetic operations except ~~divisions~~ division, both overflow and underflow shall be ignored. The value returned when either overflow or underflow occurs ~~in these case~~ is:

- for unsigned results, the exact result modulo  $2^n$
- for signed results, with the exact result being  $r$ , for operations other than division the number  $x$  in the range  $2 \underline{-} 2^{n-1} \leq x < 2^{n-1}$  that satisfies  $x \text{ congruent } r \pmod{2^n}$ .

where  $n$  is the number of bits in the result.

## 3.2.3 Stacks

### 3.2.3.1 Data stack

Objects on the data stack shall be one cell wide.

### 3.2.3.2 Control-flow stack

The control-flow stack is a last-in, first out list whose elements define the permissible matchings of control-flow words and the restrictions imposed on data-stack usage during the compilation of control structures.

The elements of the control-flow stack are system-compilation data types.

The control-flow stack may, but need not, physically exist in an implementation. If it does exist, it may be, but need not be, implemented using the data stack. The format of the control-flow stack is implementation defined.

### 3.2.3.3 Return stack

Items on the return stack shall consist of one or more cells. A system may use the return stack in an implementation-dependent manner during the compilation of definitions, during the execution of do-loops, and for storing run-time nesting information.

A program may use the return stack for temporary storage during the execution of a definition subject to the following restrictions:

- A program shall not access values on the return stack (using **R@**, **R>**, **2R@**, **2R>** or **NR>**) that it did not place there using **>R**, **2>R** or **N>R**;
- A program shall not access from within a do-loop values placed on the return stack before the loop was entered;
- All values placed on the return stack within a do-loop shall be removed before **I**, **J**, **LOOP**, **+LOOP**, **UNLOOP**, or **LEAVE** is executed;
- All values placed on the return stack within a definition shall be removed before the definition is terminated or before **EXIT** is executed.

## 3.2.4 Operator terminal

See [1.2.2 Exclusions](#).

### 3.2.4.1 User input device

The method of selecting the user input device is implementation defined.

The method of indicating the end of an input line of text is implementation defined.

### 3.2.4.2 User output device

The method of selecting the user output device is implementation defined.

## 3.2.5 Mass storage

A system need not provide any standard words for accessing mass storage.

## 3.2.6 Environmental queries

The name spaces for **ENVIRONMENT?** and definitions are disjoint. Names of definitions that are the same as **ENVIRONMENT?** strings shall not impair the operation of **ENVIRONMENT?**. Table [3.5](#) contains the

valid input strings and corresponding returned value for inquiring about the programming environment with [ENVIRONMENT?](#).

Table 3.5: Environmental Query Strings

String	Value data type	Constant?	Meaning
/COUNTED-STRING	<i>n</i>	yes	maximum size of a counted string, in characters
/HOLD	<i>n</i>	yes	size of the pictured numeric output string buffer, in characters
/PAD	<i>n</i>	yes	size of the scratch area pointed to by <a href="#">PAD</a> , in characters
ADDRESS-UNIT-BITS	<i>n</i>	yes	size of one address unit, in bits
FLOORED	<i>flag</i>	yes	true if floored division is the default
MAX-CHAR	<i>u</i>	yes	maximum value of any character in the implementation-defined character set
MAX-D	<i>d</i>	yes	largest usable signed double number
MAX-N	<i>n</i>	yes	largest usable signed integer
MAX-U	<i>u</i>	yes	largest usable unsigned integer
MAX-UD	<i>ud</i>	yes	largest usable unsigned double number
RETURN-STACK-CELLS	<i>n</i>	yes	maximum size of the return stack, in cells
STACK-CELLS	<i>n</i>	yes	maximum size of the data stack, in cells

If an environmental query (using [ENVIRONMENT?](#)) returns *false* (i.e., unknown) in response to a string, subsequent queries using the same string may return *true*. If a query returns *true* (i.e., known) in response to a string, subsequent queries with the same string shall also return *true*. If a query designated as constant in the above table returns *true* and a value in response to a string, subsequent queries with the same string shall return *true* and the same value.

### 3.2.7 Obsolescent Environmental Queries

X:wordset-query

This standard designates the practice of using [ENVIRONMENT?](#) to inquire whether a given word set is present as obsolescent. If such a query, as listed in table 3.6, returns *true*, the word set is present in the form defined by Forth 94. As these queries will be withdrawn from future revisions of the standard their use in new programs is discouraged.

See [A.3.2.7 Obsolescent Environmental Queries](#).

### 3.2.8 Extension queries

X:extension-query

As part of the Forth 200x standards procedure, additions to the standard are labeled as *extensions*. These extensions have been added to the environmental query name space. [ENVIRONMENT?](#) returns *true* if the system has implemented the extension as documented. Table 3.7 contains the valid input strings corresponding to the documented extensions. In order to distinguish such extensions, they start with the string “X:”.

The extension to the environment query table (3.2.6) is itself an extension. Known as the X:extension-query extension:

Table 3.6: Obsolescent Environmental Query Strings

String	Value data type	Constant?	Meaning
CORE	<i>flag</i>	no	true if complete core word set of Forth 94 is present (i.e., not a subset as defined in 5.1.1)
CORE-EXT	<i>flag</i>	no	true if the core extensions word set of Forth 94 is present
BLOCK	<i>flag</i>	no	Forth 94 block word set present.
BLOCK-EXT	<i>flag</i>	no	Forth 94 block extensions word set present.
DOUBLE	<i>flag</i>	no	Forth 94 double number word set present.
DOUBLE-EXT	<i>flag</i>	no	Forth 94 double number extensions word set present.
EXCEPTION	<i>flag</i>	no	Forth 94 exception word set present.
EXCEPTION-EXT	<i>flag</i>	no	Forth 94 exception extensions word set present.
FACILITY	<i>flag</i>	no	Forth 94 facility word set present.
FACILITY-EXT	<i>flag</i>	no	Forth 94 facility extensions word set present.
FILE	<i>flag</i>	no	Forth 94 file word set present.
FILE-EXT	<i>flag</i>	no	Forth 94 file extensions word set present.
FLOATING	<i>flag</i>	no	Forth 94 floating-point word set present.
FLOATING-EXT	<i>flag</i>	no	Forth 94 floating-point extensions word set present.
LOCALS	<i>flag</i>	no	Forth 94 locals word set present.
LOCALS-EXT	<i>flag</i>	no	Forth 94 locals extensions word set present.
MEMORY-ALLOC	<i>flag</i>	no	Forth 94 memory-allocation word set present.
MEMORY-ALLOC-EXT	<i>flag</i>	no	Forth 94 memory-allocation extensions word set present.
TOOLS	<i>flag</i>	no	Forth 94 programming-tools word set present.
TOOLS-EXT	<i>flag</i>	no	Forth 94 programming-tools extensions word set present.
SEARCH-ORDER	<i>flag</i>	no	Forth 94 search-order word set present.
SEARCH-ORDER-EXT	<i>flag</i>	no	Forth 94 search-order extensions word set present.
STRING	<i>flag</i>	no	Forth 94 string word set present.
STRING-EXT	<i>flag</i>	no	Forth 94 string extensions word set present.

### 3.3 The Forth dictionary

Forth words are organized into a structure called the dictionary. While the form of this structure is not specified by the standard, it can be described as consisting of three logical parts: a name space, a code space, and a data space. The logical separation of these parts does not require their physical separation.

A program shall not fetch from or store into locations outside data space. An ambiguous condition exists if a program addresses name space or code space.

#### 3.3.1 Name space

The relationship between name space and data space is implementation dependent.

##### 3.3.1.1 Word lists

The structure of a word list is implementation dependent. When duplicate names exist in a word list, the latest-defined duplicate shall be the one found during a search for the name.

Table 3.7: Forth 200x Extensions

String	Value data type	Constant?	Meaning
<del>x:2value</del>	-	-	the X:2value extension is present
<del>x:deferred</del>	-	-	the X:deferred extension is present
<del>X:defined</del>	-	-	the X:defined extension is present
<del>x:ekeys</del>	-	-	the X:ekeys extension is present
<del>x:escaped-strings</del>	-	-	the X:escaped-strings extension is present
<del>x:extension-query</del>	-	-	the X:extension-query extension is present
<del>x:fatan2</del>	-	-	the X:fatan2 extension is present
<del>x:ftrunc</del>	-	-	the X:ftrunc extension is present
<del>x:fvalue</del>	-	-	the X:fvalue extension is present
<del>x:n-to-r</del>	-	-	the x:n-to-r extension is present
<del>x:number-prefix</del>	-	-	the X:number-prefix extension is present
<del>x:parse-name</del>	-	-	the X:parse-name extension is present
<del>x:required</del>	-	-	the X:required extension is present
<del>x:structures</del>	-	-	the X:structures extension is present
<del>x:synonym</del>	-	-	the X:synonym extension is present
<del>x:throw-iors</del>	-	-	the X:throw-iors extension is present
<del>x:traverse-wordlist</del>	-	-	the X:traverse-wordlist extension is present
<del>x:xchar</del>	-	-	the X:xchar extension is present

### 3.3.1.2 Definition names

Definition names shall contain {1 ... 31} characters. A system may allow or prohibit the creation of definition names containing non-standard characters. A system may allow the creation of definition names longer than 31 characters. Programs with definition names longer than 31 characters have an environmental dependency.

Programs that use lower case for standard definition names or depend on the case-sensitivity properties of a system have an environmental dependency.

A program shall not create definition names containing non-graphic characters.

### 3.3.2 Code space

The relationship between code space and data space is implementation dependent.

### 3.3.3 Data space

Data space is the only logical area of the dictionary for which standard words are provided to allocate and access regions of memory. These regions are: contiguous regions, variables, text-literal regions, input buffers, and other transient regions, each of which is described in the following sections. A program may read from or write into these regions unless otherwise specified.

#### 3.3.3.1 Address alignment

Most addresses are cell aligned (indicated by *a-addr*) or character aligned (*c-addr*). **ALIGNED**, **CHAR+**, and arithmetic operations can alter the alignment state of an address on the stack. **CHAR+** applied to an

aligned address returns a character-aligned address that can only be used to access characters. Applying **CHAR+** to a character-aligned address produces the succeeding character-aligned address. Adding or subtracting an arbitrary number to an address can produce an unaligned address that shall not be used to fetch or store anything. The only way to find the next aligned address is with **ALIGNED**. An ambiguous condition exists when memory is accessed using an address that is not aligned according to the requirements for the accessed type.

The definitions of **6.1.1000 CREATE** and **6.1.2410 VARIABLE** require that the definitions created by them return aligned addresses.

After definitions are compiled or the word **ALIGN** is executed the data-space pointer is guaranteed to be aligned.

### 3.3.3.2 Contiguous regions

A system guarantees that a region of data space allocated using **ALLOT**, **,** (comma), **C**, (c-comma), and **ALIGN** shall be contiguous with the last region allocated with one of the above words, unless the restrictions in the following paragraphs apply. The data-space pointer **HERE** always identifies the beginning of the next data-space region to be allocated. As successive allocations are made, the data-space pointer increases. A program may perform address arithmetic within contiguously allocated regions. The last region of data space allocated using the above operators may be released by allocating a corresponding negatively-sized region using **ALLOT**, subject to the restrictions of the following paragraphs.

**CREATE** establishes the beginning of a contiguous region of data space, whose starting address is returned by the **CREATE** definition. This region is terminated by compiling the next definition.

Since an implementation is free to allocate data space for use by code, the above operators need not produce contiguous regions of data space if definitions are added to or removed from the dictionary between allocations. An ambiguous condition exists if deallocated memory contains definitions.

### 3.3.3.3 Variables

The region allocated for a variable may be non-contiguous with regions subsequently allocated with **,** (comma) or **ALLOT**. For example, in:

```
VARIABLE X 1 CELLS ALLOT
```

the region X and the region **ALLOT**ted could be non-contiguous.

Some system-provided variables, such as **STATE**, are restricted to read-only access.

### 3.3.3.4 Text-literal regions

The text-literal regions, specified by strings compiled with **S**", **S\"** and **C**", may be read-only.

A program shall not store into the text-literal regions created by **S**", **S\"** and **C**" nor into any read-only system variable or read-only transient regions.

### 3.3.3.5 Input buffers

The address, length, and content of the input buffer may be transient. A program shall not write into the input buffer. In the absence of any optional word sets providing alternative input sources, the input buffer is either the terminal-input buffer, used by **QUIT** to hold one line from the user input device, or a buffer

specified by **EVALUATE**. In all cases, **SOURCE** returns the beginning address and length in characters of the current input buffer.

The minimum size of the terminal-input buffer shall be 80 characters.

The address and length returned by **SOURCE**, the string returned by **PARSE**, and directly computed input-buffer addresses are valid only until the text interpreter does I/O to refill the input buffer or the input source is changed.

A program may modify the size of the parse area by changing the contents of **>IN** within the limits imposed by this standard. For example, if the contents of **>IN** are saved before a parsing operation and restored afterwards, the text that was parsed will be available again for subsequent parsing operations. The extent of permissible repositioning using this method depends on the input source (see **7.3.2 Block buffer regions** and **11.3.3 Input source**).

A program may directly examine the input buffer using its address and length as returned by **SOURCE**; the beginning of the parse area within the input buffer is indexed by the number in **>IN**. The values are valid for a limited time. An ambiguous condition exists if a program modifies the contents of the input buffer.

### 3.3.3.6 Other transient regions

The data space regions identified by **PAD**, **WORD**, and **#>** (the pictured numeric output string buffer) may be transient. Their addresses and contents may become invalid after:

- a definition is created via a defining word;
- definitions are compiled with **:** or **:NONAME**;
- data space is allocated using **ALLOT**, **,** (comma), **C**, (c-comma), or **ALIGN**.

The previous contents of the regions identified by **WORD** and **#>** may be invalid after each use of these words. Further, the regions returned by **WORD** and **#>** may overlap in memory. Consequently, use of one of these words can corrupt a region returned earlier by a different word. The other words that construct pictured numeric output strings (**<#**, **#**, **#S**, **HOLD**, **HOLDS**, **XHOLD**) may also modify the contents of these regions. Words that display numbers may be implemented using pictured numeric output words. Consequently, **.** (dot), **.R**, **.S**, **?**, **D.**, **D.R**, **U.**, **U.R** could also corrupt the regions.

The size of the scratch area whose address is returned by **PAD** shall be at least 84 characters. The contents of the region addressed by **PAD** are intended to be under the complete control of the user: no words defined in this standard place anything in the region, although changing data-space allocations as described in **3.3.3.2 Contiguous regions** may change the address returned by **PAD**. Non-standard words provided by an implementation may use **PAD**, but such use shall be documented.

The size of the region identified by **WORD** shall be at least 33 characters.

The size of the pictured numeric output string buffer shall be at least  $(2 \times n) + 2$  characters, where  $n$  is the number of bits in a cell. Programs that consider it a fixed area with unchanging access parameters have an environmental dependency.

## 3.4 The Forth text interpreter

Upon start-up, a system shall be able to interpret, as described by [6.1.2050 QUIT](#), Forth source code received interactively from a user input device.

Such interactive systems usually furnish a “prompt” indicating that they have accepted a user request and acted on it. The implementation-defined Forth prompt should contain the word “OK” in some combination of upper or lower case.

Text interpretation (see [6.1.1360 EVALUATE](#) and [6.1.2050 QUIT](#)) shall repeat the following steps until either the parse area is empty or an ambiguous condition exists:

- a) Skip leading spaces and parse a *name* (see [3.4.1](#));
- b) Search the dictionary name space (see [3.4.2](#)). If a definition name matching the string is found:
  - 1) if interpreting, perform the interpretation semantics of the definition (see [3.4.3.2](#)), and continue at a).
  - 2) if compiling, perform the compilation semantics of the definition (see [3.4.3.3](#)), and continue at a).
- c) If a definition name matching the string is not found, attempt to convert the string to a number (see [3.4.1.3](#)). If successful:
  - 1) if interpreting, place the number on the data stack, and continue at a);
  - 2) if compiling, compile code that when executed will place the number on the stack (see [6.1.1780 LITERAL](#)), and continue at a);
- d) If unsuccessful, an ambiguous condition exists (see [3.4.4](#)).

### 3.4.1 Parsing

Unless otherwise noted, the number of characters parsed may be from zero to the implementation-defined maximum length of a counted string.

If the parse area is empty, i.e., when the number in **>IN** is equal to the length of the input buffer, or contains no characters other than delimiters, the selected string is empty. Otherwise, the selected string begins with the next character in the parse area, which is the character indexed by the contents of **>IN**. An ambiguous condition exists if the number in **>IN** is greater than the size of the input buffer.

If delimiter characters are present in the parse area after the beginning of the selected string, the string continues up to and including the character just before the first such delimiter, and the number in **>IN** is changed to index immediately past that delimiter, thus removing the parsed characters and the delimiter from the parse area. Otherwise, the string continues up to and including the last character in the parse area, and the number in **>IN** is changed to the length of the input buffer, thus emptying the parse area.

Parsing may change the contents of **>IN**, but shall not affect the contents of the input buffer. Specifically, if the value in **>IN** is saved before starting the parse, resetting **>IN** to that value immediately after the parse shall restore the parse area without loss of data.

### 3.4.1.1 Delimiters

If the delimiter is the space character, hex 20 (**BL**), control characters may be treated as delimiters. The set of conditions, if any, under which a “space” delimiter matches control characters is implementation defined.

To skip leading delimiters is to pass by zero or more contiguous delimiters in the parse area before parsing.

### 3.4.1.2 Syntax

Forth has a simple, operator-ordered syntax. The phrase *A B C* returns values as if *A* were executed first, then *B* and finally *C*. Words that cause deviations from this linear flow of control are called control-flow words. Combinations of control-flow words whose stack effects are compatible form control-flow structures. Examples of typical use are given for each control-flow word in Annex A.

Forth syntax is extensible; for example, new control-flow words can be defined in terms of existing ones. This standard does not require a syntax or program-construct checker.

### 3.4.1.3 Text interpreter input number conversion

When converting input numbers, the text interpreter shall recognize integer numbers in the form  $\langle anynum \rangle$ .

$$\begin{aligned} \langle anynum \rangle &:= \{ \langle BASEnum \rangle \mid \langle decnum \rangle \mid \langle hexnum \rangle \mid \langle binnum \rangle \mid \langle cnum \rangle \} \\ \langle BASEnum \rangle &:= [-] \langle bdigit \rangle \langle bdigit \rangle^* \\ \langle decnum \rangle &:= \# [-] \langle decdigit \rangle \langle decdigit \rangle^* \\ \langle hexnum \rangle &:= \$ [-] \langle hexdigit \rangle \langle hexdigit \rangle^* \\ \langle binnum \rangle &:= \% [-] \langle bindigit \rangle \langle bindigit \rangle^* \\ \langle cnum \rangle &:= ' \langle char \rangle ' \\ \langle bindigit \rangle &:= \{ \mathbf{0} \mid \mathbf{1} \} \\ \langle decdigit \rangle &:= \{ \mathbf{0} \mid \mathbf{1} \mid \mathbf{2} \mid \mathbf{3} \mid \mathbf{4} \mid \mathbf{5} \mid \mathbf{6} \mid \mathbf{7} \mid \mathbf{8} \mid \mathbf{9} \} \\ \langle hexdigit \rangle &:= \{ \langle decdigit \rangle \mid \mathbf{a} \mid \mathbf{b} \mid \mathbf{c} \mid \mathbf{d} \mid \mathbf{e} \mid \mathbf{f} \mid \mathbf{A} \mid \mathbf{B} \mid \mathbf{C} \mid \mathbf{D} \mid \mathbf{E} \mid \mathbf{F} \} \end{aligned}$$

$\langle bdigit \rangle$  represents a digit according to the value of **BASE** (see 3.2.1.2 Digit conversion). For  $\langle hexdigit \rangle$ , the digits **a**...**f** have the values 10...15.  $\langle char \rangle$  represents any printable character.

The radix used for number conversion is:

$\langle BASEnum \rangle$	the value in <b>BASE</b>
$\langle decnum \rangle$	10
$\langle hexnum \rangle$	16
$\langle binnum \rangle$	2
$\langle cnum \rangle$	the number is the value of $\langle char \rangle$

See 2.2.5 BNF notation.

## 3.4.2 Finding definition names

A string matches a definition name if each character in the string matches the corresponding character in the string used as the definition name when the definition was created. The case sensitivity (whether or not the upper-case letters match the lower-case letters) is implementation defined. A system may be either case sensitive, treating upper- and lower-case letters as different and not matching, or case insensitive, ignoring differences in case while searching.

The matching of upper- and lower-case letters with alphabetic characters in character set extensions such as accented international characters is implementation defined.

A system shall be capable of finding the definition names defined by this standard when they are spelled with upper-case letters.

### 3.4.3 Semantics

The semantics of a Forth definition are implemented by machine code or a sequence of execution tokens or other representations. They are largely specified by the stack notation in the glossary entries, which shows what values shall be consumed and produced. The prose in each glossary entry further specifies the definition's behavior.

Each Forth definition may have several behaviors, described in the following sections. The terms "initiation semantics" and "run-time semantics" refer to definition fragments, and have meaning only within the individual glossary entries where they appear.

#### 3.4.3.1 Execution semantics

The execution semantics of each Forth definition are specified in an "Execution:" section of its glossary entry. When a definition has only one specified behavior, the label is omitted.

Execution may occur implicitly, when the definition into which it has been compiled is executed, or explicitly, when its execution token is passed to **EXECUTE**. The execution semantics of a syntactically correct definition under conditions other than those specified in this standard are implementation dependent.

Glossary entries for defining words include the execution semantics for the new definition in a "*name* Execution:" section.

#### 3.4.3.2 Interpretation semantics

Unless otherwise specified in an "Interpretation:" section of the glossary entry, the interpretation semantics of a Forth definition are its execution semantics.

A system shall be capable of executing, in interpretation state, all of the definitions from the Core word set and any definitions included from the optional word sets or word set extensions whose interpretation semantics are defined by this standard.

A system shall be capable of executing, in interpretation state, any new definitions created in accordance with **3 Usage requirements**.

#### 3.4.3.3 Compilation semantics

Unless otherwise specified in a "Compilation:" section of the glossary entry, the compilation semantics of a Forth definition shall be to append its execution semantics to the execution semantics of the current definition.

### 3.4.4 Possible actions on an ambiguous condition

When an ambiguous condition exists, a system may take one or more of the following actions:

- ignore and continue;

- display a message;
- execute a particular word;
- set interpretation state and begin text interpretation;
- take other implementation-defined actions;
- take implementation-dependent actions.

The response to a particular ambiguous condition need not be the same under all circumstances.

### 3.4.5 Compilation

A program shall not attempt to nest compilation of definitions.

During the compilation of the current definition, a program shall not execute any defining word, **:NONAME**, or any definition that allocates dictionary data space. The compilation of the current definition may be suspended using **[** (left-bracket) and resumed using **]** (right-bracket). While the compilation of the current definition is suspended, a program shall not execute any defining word, **:NONAME**, or any definition that allocates dictionary data space.

## 4 Documentation requirements

When it is impossible or infeasible for a system or program to define a particular behavior itself, it is permissible to state that the behavior is unspecified and to explain the circumstances and reasons why this is so.

### 4.1 System documentation

#### 4.1.1 Implementation-defined options

The implementation-defined items in the following list represent characteristics and choices left to the discretion of the implementor, provided that the requirements of this standard are met. A system shall document the values for, or behaviors of, each item.

- aligned address requirements [3.1.3.3 Addresses](#);
- behavior of [6.1.1320 EMIT](#) for non-graphic characters;
- character editing of [6.1.0695 ACCEPT](#);
- character set ([3.1.2 Character types](#), [6.1.1320 EMIT](#), [6.1.1750 KEY](#));
- character-aligned address requirements ([3.1.3.3 Addresses](#));
- character-set-extensions matching characteristics ([3.4.2 Finding definition names](#));
- conditions under which control characters match a space delimiter ([3.4.1.1 Delimiters](#));
- format of the control-flow stack ([3.2.3.2 Control-flow stack](#));
- conversion of digits larger than thirty-five ([3.2.1.2 Digit conversion](#));
- display after input terminates in [6.1.0695 ACCEPT](#);
- exception abort sequence (as in [6.1.0680 ABORT](#));
- input line terminator ([3.2.4.1 User input device](#));
- maximum size of a counted string, in characters ([3.1.3.4 Counted strings](#), [6.1.2450 WORD](#));
- maximum size of a parsed string ([3.4.1 Parsing](#));
- maximum size of a definition name, in characters ([3.3.1.2 Definition names](#));
- maximum string length for [6.1.1345 ENVIRONMENT?](#), in characters;
- method of selecting [3.2.4.1 User input device](#);
- method of selecting [3.2.4.2 User output device](#);
- methods of dictionary compilation ([3.3 The Forth dictionary](#));
- number of bits in one address unit ([3.1.3.3 Addresses](#));
- number representation and arithmetic ([3.2.1.1 Internal number representation](#));

- ranges for  $n$ ,  $+n$ ,  $u$ ,  $d$ ,  $+d$ , and  $ud$  ([3.1.3 Single-cell types](#), [3.1.4 Cell-pair types](#));
- read-only data-space regions ([3.3.3 Data space](#));
- size of buffer at [6.1.2450 WORD](#) ([3.3.3.6 Other transient regions](#));
- size of one cell in address units ([3.1.3 Single-cell types](#));
- size of one character in address units ([3.1.2 Character types](#));
- size of the keyboard terminal input buffer ([3.3.3.5 Input buffers](#));
- size of the pictured numeric output string buffer ([3.3.3.6 Other transient regions](#));
- size of the scratch area whose address is returned by [6.2.2000 PAD](#) ([3.3.3.6 Other transient regions](#));
- system case-sensitivity characteristics ([3.4.2 Finding definition names](#));
- system prompt ([3.3 The Forth dictionary](#), [6.1.2050 QUIT](#));
- type of division rounding ([3.2.2.1 Integer division](#), [6.1.0100 \\*/](#), [6.1.0110 \\*/MOD](#), [6.1.0230 /](#), [6.1.0240 /MOD](#), [6.1.1890 MOD](#));
- values of [6.1.2250 STATE](#) when true;
- whether the current definition can be found after [6.1.1250 DOES>](#) ([6.1.0450 :](#)).

#### 4.1.2 Ambiguous conditions

A system shall document the system action taken upon each of the general or specific ambiguous conditions identified in this standard. See [3.4.4 Possible actions on an ambiguous condition](#).

The following general ambiguous conditions could occur because of a combination of factors:

- a *name* is neither a valid definition name nor a valid number during text interpretation ([3.4 The Forth text interpreter](#));
- a definition name exceeded the maximum length allowed ([3.3.1.2 Definition names](#));
- addressing a region not listed in [3.3.3 Data space](#);
- argument type incompatible with specified input parameter, e.g., passing a *flag* to a word expecting an  $n$  ([3.1 Data types](#));
- attempting to obtain the execution token, (e.g., with [6.1.0070 ' , 6.1.1550 FIND](#), etc. of a definition with undefined interpretation semantics);
- dividing by zero ([6.1.0100 \\*/](#), [6.1.0110 \\*/MOD](#), [6.1.0230 /](#), [6.1.0240 /MOD](#), [6.1.1561 FM/MOD](#), [6.1.1890 MOD](#), [6.1.2214 SM/REM](#), [6.1.2370 UM/MOD](#), [8.6.1.1820 M\\*/](#));
- insufficient data-stack space or return-stack space (stack overflow);
- insufficient space for loop-control parameters;
- insufficient space in the dictionary;
- interpreting a word with undefined interpretation semantics;

- modifying the contents of the input buffer or a string literal ([3.3.3.4 Text-literal regions](#), [3.3.3.5 Input buffers](#));
- overflow of a pictured numeric output string;
- parsed string overflow;
- producing a result out of range, e.g., multiplication (using `*`) results in a value too big to be represented by a single-cell integer ([6.1.0090 \\*](#), [6.1.0100 \\*/](#), [6.1.0110 \\*/MOD](#), [6.1.0570 >NUMBER](#), [6.1.1561 FM/MOD](#), [6.1.2214 SM/REM](#), [6.1.2370 UM/MOD](#), [8.6.1.1820 M\\*/](#));
- reading from an empty data stack or return stack (stack underflow);
- unexpected end of input buffer, resulting in an attempt to use a zero-length string as a *name*.

The following specific ambiguous conditions are noted in the glossary entries of the relevant words:

- `>IN` greater than size of input buffer ([3.4.1 Parsing](#));
- [6.1.2120 RECURSE](#) appears after [6.1.1250 DOES>](#);
- argument input source different than current input source for [6.2.2148 RESTORE-INPUT](#);
- data space containing definitions is de-allocated ([3.3.3.2 Contiguous regions](#));
- data space read/write with incorrect alignment ([3.3.3.1 Address alignment](#));
- data-space pointer not properly aligned ([6.1.0150 ,](#) , [6.1.0860 C,](#) );
- less than  $u+2$  stack items ([6.2.2030 PICK](#), [6.2.2150 ROLL](#));
- loop-control parameters not available ([6.1.0140 +LOOP](#), [6.1.1680 I](#), [6.1.1730 J](#), [6.1.1760 LEAVE](#), [6.1.1800 LOOP](#), [6.1.2380 UNLOOP](#));
- most recent definition does not have a *name* ([6.1.1710 IMMEDIATE](#));
- [6.2.2295 TO](#) not followed directly by a *name* defined by a word with “`TO name` runtime” semantics ([6.2.2405 VALUE](#) and [13.6.1.0086 \(LOCAL\)](#));
- *name* not found [6.1.0070 ' ,](#) [6.1.2033 POSTPONE](#), [6.1.2510 \[ ' \]](#), [6.2.2530 \[ COMPILER \]](#));
- parameters are not of the same type [6.1.1240 DO](#), [6.2.0620 ?DO](#), [6.2.2440 WITHIN](#));
- [6.1.2033 POSTPONE](#), [6.2.2530 \[ COMPILER \]](#), [6.1.0070 ' or](#) [6.1.2510 \[ ' \]](#) applied to [6.2.2295 TO](#);
- string longer than a counted string returned by [6.1.2450 WORD](#);
- $u$  greater than or equal to the number of bits in a cell ([6.1.1805 LSHIFT](#), [6.1.2162 RSHIFT](#));
- word not defined via [6.1.1000 CREATE](#) ([6.1.0550 >BODY](#), [6.1.1250 DOES>](#));
- words improperly used outside [6.1.0490 <#](#) and [6.1.0040 #>](#) ([6.1.0030 #](#), [6.1.0050 #S](#), [6.1.1670 HOLD](#), [6.2.1675 HOLDS](#), [6.1.2210 SIGN](#));
- access to a deferred word, a word defined by [6.2.1173 DEFER](#), which has yet to be assigned to an *xt*;
- access to a deferred word, a word defined by [6.2.1173 DEFER](#), which was not defined by [6.2.1173 DEFER](#);

- [6.1.2033](#) `POSTPONE`, [6.2.2530](#) `[COMPILE]`, [6.1.2510](#) `[ ' ]` or [6.1.0070](#) `'` applied to [6.2.0698](#) `ACTION-OF` or [6.2.1725](#) `IS`;
- `\x` is not followed by two hexadecimal characters ([6.2.2266](#) `S\`");
- a `\` is placed before any character, other than those defined in [6.2.2266](#) `S\`".

### 4.1.3 Other system documentation

A system shall provide the following information:

- list of non-standard words using [6.2.2000](#) `PAD` ([3.3.3.6 Other transient regions](#));
- operator's terminal facilities available;
- program data space available, in address units;
- return stack space available, in cells;
- stack space available, in cells;
- system dictionary space required, in address units.

## 4.2 Program documentation

### 4.2.1 Environmental dependencies

A program shall document the following environmental dependencies, where they apply, and should document other known environmental dependencies:

- considering the pictured numeric output string buffer a fixed area with unchanging access parameters ([3.3.3.6 Other transient regions](#));
- depending on the presence or absence of non-graphic characters in a received string ([6.1.0695](#) `ACCEPT`);
- relying on a particular rounding direction ([3.2.2.1 Integer division](#));
- requiring a particular number representation and arithmetic ([3.2.1.1 Internal number representation](#));
- requiring non-standard words or techniques ([3 Usage requirements](#));
- requiring the ability to send or receive control characters ([3.1.2.2 Control characters](#), [6.1.1750](#) `KEY`);
- using control characters to perform specific functions [6.1.1320](#) `EMIT`, [6.1.2310](#) `TYPE`);
- using flags as arithmetic operands ([3.1.3.1 Flags](#));
- using lower case for standard definition names or depending on the case sensitivity of a system ([3.3.1.2 Definition names](#));
- using definition names of more than 31 characters in length ([3.3.1.2 Definition names](#));
- using the graphic character with a value of hex 24 ([3.1.2.1 Graphic characters](#)).

**4.2.2 Other program documentation**

A program shall also document:

- minimum operator's terminal facilities required;
- whether a Standard System exists after the program is loaded.

## 5 Compliance and labeling

### 5.1 Forth-2012 systems

#### 5.1.1 System compliance

A system that complies with all the system requirements given in sections [3 Usage requirements](#) and [4.1 System documentation](#) and their sub-sections is a Standard System. An otherwise Standard System that provides only a portion of the Core words is a Standard System Subset. An otherwise Standard System (Subset) that fails to comply with one or more of the minimum values or ranges specified in [3 Usage requirements](#) and its sub-sections has environmental restrictions.

#### 5.1.2 System labeling

A Standard System (Subset) shall be labeled a “Forth-2012 System (Subset)”. That label, by itself, shall not be applied to Standard Systems or Standard System Subsets that have environmental restrictions.

The phrase “with Environmental Restrictions” shall be appended to the label of a Standard System (Subset) that has environmental restrictions.

The phrase “Providing *name(s)* from the Core Extensions word set” shall be appended to the label of any Standard System that provides portions of the Core Extensions word set.

The phrase “Providing the Core Extensions word set” shall be appended to the label of any Standard System that provides all of the Core Extensions word set.

### 5.2 Forth-2012 programs

#### 5.2.1 Program compliance

A program that complies with all the program requirements given in sections [3 Usage requirements](#) and [4.2 Program documentation](#) and their sub-sections is a Standard Program.

#### 5.2.2 Program labeling

A Standard Program shall be labeled a “Forth-2012 Program”. That label, by itself, shall not be applied to Standard Programs that require the system to provide standard words outside the Core word set or that have environmental dependencies.

The phrase “with Environmental Dependencies” shall be appended to the label of Standard Programs that have environmental dependencies.

The phrase “Requiring *name(s)* from the Core Extensions word set” shall be appended to the label of Standard Programs that require the system to provide portions of the Core Extensions word set.

The phrase “Requiring the Core Extensions word set” shall be appended to the label of Standard Programs that require the system to provide all of the Core Extensions word set.

exists if  $n_3$  is zero, or if the quotient  $n_5$  lies outside the range of a single-cell signed integer. If  $d$  and  $n_3$  differ in sign, the implementation-defined result returned will be the same as that returned by either the phrase **>R M\* R> FM/MOD** or the phrase **>R M\* R> SM/REM**.

See: [3.2.2.1 Integer division](#).

**6.1.0120**    **+**    “plus”    CORE

$( n_1 \mid u_1 \ n_2 \mid u_2 \ -- \ n_3 \mid u_3 )$

Add  $n_2 \mid u_2$  to  $n_1 \mid u_1$ , giving the sum  $n_3 \mid u_3$ .

See: [3.3.3.1 Address alignment](#).

**6.1.0130**    **+**!    “plus-store”    CORE

$( n \mid u \ a\text{-}addr \ -- \ )$

Add  $n \mid u$  to the single-cell number at *a-addr*.

See: [3.3.3.1 Address alignment](#).

**6.1.0140**    **+LOOP**    “plus-loop”    CORE

Interpretation: Interpretation semantics for this word are undefined.

Compilation:  $( C: \ do\text{-}sys \ -- \ )$

Append the run-time semantics given below to the current definition. Resolve the destination of all unresolved occurrences of **LEAVE** between the location given by *do-sys* and the next location for a transfer of control, to execute the words following **+LOOP**.

Run-time:  $( n \ -- \ ) \ ( R: \ loop\text{-}sys_1 \ -- \ \mid \ loop\text{-}sys_2 \ )$

An ambiguous condition exists if the loop control parameters are unavailable. Add  $n$  to the loop index. If the loop index did not cross the boundary between the loop limit minus one and the loop limit, continue execution at the beginning of the loop. Otherwise, discard the current loop control parameters and continue execution immediately following the loop.

See: [6.1.1240 DO](#), [6.1.1680 I](#), [6.1.1760 LEAVE](#), [A.6.1.0140 +LOOP](#).

- 6.1.0150** , “comma” CORE  
 $( x -- )$   
 Reserve one cell of data space and store  $x$  in the cell. If the data-space pointer is aligned when `,` begins execution, it will remain aligned when `,` finishes execution. An ambiguous condition exists if the data-space pointer is not aligned prior to execution of `,`.  
 See: [3.3.3 Data space](#), [3.3.3.1 Address alignment](#), [A.6.1.0150 ,](#).
- 6.1.0160** - “minus” CORE  
 $( n_1 | u_1 n_2 | u_2 -- n_3 | u_3 )$   
 Subtract  $n_2 | u_2$  from  $n_1 | u_1$ , giving the difference  $n_3 | u_3$ .  
 See: [3.3.3.1 Address alignment](#).
- 6.1.0180** . “dot” CORE  
 $( n -- )$   
 Display  $n$  in free field format.  
 See: [3.2.1.2 Digit conversion](#), [3.2.1.3 Free-field number display](#).
- 6.1.0190** ." “dot-quote” CORE  
 Interpretation: Interpretation semantics for this word are undefined.  
 Compilation: ( `ccc<quote>` ) -- )  
 Parse `ccc` delimited by `"` (double-quote). Append the run-time semantics given below to the current definition.  
 Run-time: ( -- )  
 Display `ccc`.  
 See: [3.4.1 Parsing](#), [6.2.0200 . \(](#), [A.6.1.0190 . "](#).
- 6.1.0230** / “slash” CORE  
 $( n_1 n_2 -- n_3 )$   
 Divide  $n_1$  by  $n_2$ , giving the single-cell quotient  $n_3$ . An ambiguous condition exists if  $n_2$  is zero. If  $n_1$  and  $n_2$  differ in sign, the implementation-defined result returned will be the same as that returned by either the phrase `>R S>D R> FM/MOD SWAP DROP` or the phrase `>R S>D R> SM/REM SWAP DROP`.  
 See: [3.2.2.1 Integer division](#).

<b>6.1.0240</b>	<b>/MOD</b>	“slash-mod”	CORE
		$( n_1 n_2 -- n_3 n_4 )$	
		Divide $n_1$ by $n_2$ , giving the single-cell remainder $n_3$ and the single-cell quotient $n_4$ . An ambiguous condition exists if $n_2$ is zero. If $n_1$ and $n_2$ differ in sign, the implementation-defined result returned will be the same as that returned by either the phrase <b>&gt;R S&gt;D R&gt; FM/MOD</b> or the phrase <b>&gt;R S&gt;D R&gt; SM/REM</b> .	
		See: <b>3.2.2.1 Integer division</b> .	
<b>6.1.0250</b>	<b>0&lt;</b>	“zero-less”	CORE
		$( n -- flag )$	
		<i>flag</i> is true if and only if $n$ is less than zero.	
<b>6.1.0270</b>	<b>0=</b>	“zero-equals”	CORE
		$( x -- flag )$	
		<i>flag</i> is true if and only if $x$ is equal to zero.	
<b>6.1.0290</b>	<b>1+</b>	“one-plus”	CORE
		$( n_1   u_1 -- n_2   u_2 )$	
		Add one (1) to $n_1   u_1$ giving the sum $n_2   u_2$ .	
<b>6.1.0300</b>	<b>1-</b>	“one-minus”	CORE
		$( n_1   u_1 -- n_2   u_2 )$	
		Subtract one (1) from $n_1   u_1$ giving the difference $n_2   u_2$ .	
<b>6.1.0310</b>	<b>2!</b>	“two-store”	CORE
		$( x_1 x_2 a-addr -- )$	
		Store the cell pair $x_1 x_2$ at <i>a-addr</i> , with $x_2$ at <i>a-addr</i> and $x_1$ at the next consecutive cell. It is equivalent to the sequence <b>SWAP OVER ! CELL+ !</b> .	
		See: <b>3.3.3.1 Address alignment</b> .	

<b>6.1.0320</b>	<b>2*</b>	“two-star”	CORE
		$(x_1 -- x_2)$	
		$x_2$ is the result of shifting $x_1$ one bit toward the most-significant bit, filling the vacated least-significant bit with zero.	
<b>6.1.0330</b>	<b>2/</b>	“two-slash”	CORE
		$(x_1 -- x_2)$	
		$x_2$ is the result of shifting $x_1$ one bit toward the least-significant bit, leaving the most-significant bit unchanged.	
<b>6.1.0350</b>	<b>2@</b>	“two-fetch”	CORE
		$(a-addr -- x_1 x_2)$	
		Fetch the cell pair $x_1 x_2$ stored at $a-addr$ . $x_2$ is stored at $a-addr$ and $x_1$ at the next consecutive cell. It is equivalent to the sequence <b>DUP CELL+ @ SWAP @</b> .	
		See: <a href="#">3.3.3.1 Address alignment</a> , <a href="#">6.1.0310 2!</a> .	
<b>6.1.0370</b>	<b>2DROP</b>	“two-drop”	CORE
		$(x_1 x_2 -- )$	
		Drop cell pair $x_1 x_2$ from the stack.	
<b>6.1.0380</b>	<b>2DUP</b>	“two-dupe”	CORE
		$(x_1 x_2 -- x_1 x_2 x_1 x_2)$	
		Duplicate cell pair $x_1 x_2$ .	
<b>6.1.0400</b>	<b>2OVER</b>	“two-over”	CORE
		$(x_1 x_2 x_3 x_4 -- x_1 x_2 x_3 x_4 x_1 x_2)$	
		Copy cell pair $x_1 x_2$ to the top of the stack.	
<b>6.1.0430</b>	<b>2SWAP</b>	“two-swap”	CORE
		$(x_1 x_2 x_3 x_4 -- x_3 x_4 x_1 x_2)$	
		Exchange the top two cell pairs.	

<b>6.1.0490</b>	<b>&lt;#</b>	“less-number-sign”	CORE
	( -- )		
		Initialize the pictured numeric output conversion process.	
		See: <a href="#">6.1.0030 #</a> , <a href="#">6.1.0040 #&gt;</a> , <a href="#">6.1.0050 #S</a> .	
<b>6.1.0530</b>	<b>=</b>	“equals”	CORE
	( $x_1$ $x_2$ -- flag )		
		<i>flag</i> is true if and only if $x_1$ is bit-for-bit the same as $x_2$ .	
<b>6.1.0540</b>	<b>&gt;</b>	“greater-than”	CORE
	( $n_1$ $n_2$ -- flag )		
		<i>flag</i> is true if and only if $n_1$ is greater than $n_2$ .	
		See: <a href="#">6.2.2350 U&gt;</a> .	
<b>6.1.0550</b>	<b>&gt;BODY</b>	“to-body”	CORE
	( $xt$ -- <i>a-addr</i> )		
		<i>a-addr</i> is the data-field address corresponding to $xt$ . An ambiguous condition exists if $xt$ is not for a word defined via <b>CREATE</b> .	
		See: <a href="#">3.3.3 Data space</a> , <a href="#">A.6.1.0550 &gt;BODY</a> .	
<b>6.1.0560</b>	<b>&gt;IN</b>	“to-in”	CORE
	( -- <i>a-addr</i> )		
		<i>a-addr</i> is the address of a cell containing the offset in characters from the start of the input buffer to the start of the parse area.	
<b>6.1.0570</b>	<b>&gt;NUMBER</b>	“to-number”	CORE
	( $ud_1$ <i>c-addr</i> <sub>1</sub> $u_1$ -- $ud_2$ <i>c-addr</i> <sub>2</sub> $u_2$ )		
		$ud_2$ is the unsigned result of converting the characters within the string specified by <i>c-addr</i> <sub>1</sub> $u_1$ into digits, using the number in <b>BASE</b> , and adding each into $ud_1$ after multiplying $ud_1$ by the number in <b>BASE</b> . Conversion continues left-to-right until a character that is not convertible, including any “+” or “-”, is encountered or the string is entirely converted. <i>c-addr</i> <sub>2</sub> is the location of the first unconverted character or the first character	

past the end of the string if the string was entirely converted.  $u_2$  is the number of unconverted characters in the string. An ambiguous condition exists if  $ud_2$  overflows during the conversion.

See: [3.2.1.2 Digit conversion](#).

**6.1.0580**    **>R**    "to-r"    CORE

Interpretation: Interpretation semantics for this word are undefined.

Execution:  $(x \text{-- } ) (R: \text{-- } x)$

Move  $x$  to the return stack.

See: [3.2.3.3 Return stack](#), [6.1.2060 R>](#), [6.1.2070 R@](#), [6.2.0340 2>R](#), [6.2.0410 2R>](#), [6.2.0415 2R@](#).

**6.1.0630**    **?DUP**    "question-dupe"    CORE

$(x \text{-- } 0 \mid x x)$

Duplicate  $x$  if it is non-zero.

**6.1.0650**    **@**    "fetch"    CORE

$(a\text{-addr} \text{-- } x)$

$x$  is the value stored at  $a\text{-addr}$ .

See: [3.3.3.1 Address alignment](#).

**6.1.0670**    **ABORT**    CORE

$(i * x \text{-- } ) (R: j * x \text{-- } )$

Empty the data stack and perform the function of [QUIT](#), which includes emptying the return stack, without displaying a message.

See: [9.6.2.0670 ABORT](#).

**6.1.0680**    **ABORT"**    "abort-quote"    CORE

Interpretation: Interpretation semantics for this word are undefined.

Compilation:  $(\text{"ccc}\langle\text{quote}\rangle\text{-- } )$

Parse  $ccc$  delimited by a " (double-quote). Append the run-time semantics given below to the current definition.

Run-time: (*i*\**x* *x*<sub>*l*</sub> -- | *i*\**x*) (R: *j*\**x* -- | *j*\**x*)

Remove *x*<sub>*l*</sub> from the stack. If any bit of *x*<sub>*l*</sub> is not zero, display *ccc* and perform an implementation-defined abort sequence that includes the function of **ABORT**.

See: [3.4.1 Parsing](#), [9.6.2.0680 ABORT](#)", [A.6.1.0680 ABORT](#)".

**6.1.0690 ABS** "abs" CORE

( *n* -- *u* )

*u* is the absolute value of *n*.

**6.1.0695 ACCEPT** CORE

( *c-addr* +*n*<sub>1</sub> -- +*n*<sub>2</sub> )

Receive a string of at most +*n*<sub>1</sub> characters. An ambiguous condition exists if +*n*<sub>1</sub> is zero or greater than 32,767. Display graphic characters as they are received. A program that depends on the presence or absence of non-graphic characters in the string has an environmental dependency. The editing functions, if any, that the system performs in order to construct the string are implementation-defined.

Input terminates when an implementation-defined line terminator is received. When input terminates, nothing is appended to the string, and the display is maintained in an implementation-defined way.

+*n*<sub>2</sub> is the length of the string stored at *c-addr*.

See: [A.6.1.0695 ACCEPT](#).

**6.1.0705 ALIGN** CORE

( -- )

If the data-space pointer is not aligned, reserve enough space to align it.

See: [3.3.3 Data space](#), [3.3.3.1 Address alignment](#), [A.6.1.0705 ALIGN](#).

**6.1.0706 ALIGNED** CORE

( *addr* -- *a-addr* )

*a-addr* is the first aligned address greater than or equal to *addr*.

See: [3.3.3.1 Address alignment](#), [6.1.0705 ALIGN](#).

**6.1.0710 ALLOT** CORE

( *n* -- )

If *n* is greater than zero, reserve *n* address units of data space. If *n* is less than zero, release  $|n|$  address units of data space. If *n* is zero, leave the data-space pointer unchanged.

If the data-space pointer is aligned and *n* is a multiple of the size of a cell when **ALLOT** begins execution, it will remain aligned when **ALLOT** finishes execution.

If the data-space pointer is character aligned and *n* is a multiple of the size of a character when **ALLOT** begins execution, it will remain character aligned when **ALLOT** finishes execution.

See: [3.3.3 Data space](#).

**6.1.0720 AND** CORE

( *x*<sub>1</sub> *x*<sub>2</sub> -- *x*<sub>3</sub> )

*x*<sub>3</sub> is the bit-by-bit logical “and” of *x*<sub>1</sub> with *x*<sub>2</sub>.

**6.1.0750 BASE** CORE

( -- *a-addr* )

*a-addr* is the address of a cell containing the current number-conversion radix {{2...36}}.

**6.1.0760 BEGIN** CORE

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: -- *dest* )

Put the next location for a transfer of control, *dest*, onto the control flow stack. Append the run-time semantics given below to the current definition.

Run-time: ( -- )

Continue execution.

See: [3.2.3.2 Control-flow stack](#), [6.1.2140 REPEAT](#), [6.1.2390 UNTIL](#), [6.1.2430 WHILE](#), [A.6.1.0760 BEGIN](#).

**6.1.0770 BL** CORE “b-l”

( -- *char* )

*char* is the character value for a space.

See: [A.6.1.0770 BL](#).

**6.1.1310 ELSE** CORE

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: *orig*<sub>1</sub> -- *orig*<sub>2</sub> )

Put the location of a new unresolved forward reference *orig*<sub>2</sub> onto the control flow stack. Append the run-time semantics given below to the current definition. The semantics will be incomplete until *orig*<sub>2</sub> is resolved (e.g., by **THEN**). Resolve the forward reference *orig*<sub>1</sub> using the location following the appended run-time semantics.

Run-time: ( -- )

Continue execution at the location given by the resolution of *orig*<sub>2</sub>.

See: [6.1.1700 IF](#), [6.1.2270 THEN](#), [A.6.1.1310 ELSE](#).

**6.1.1320 EMIT** CORE

( *x* -- )

If *x* is a graphic character in the implementation-defined character set, display *x*. The effect of **EMIT** for all other values of *x* is implementation-defined.

When passed a character whose character-defining bits have a value between hex 20 and 7E inclusive, the corresponding standard character, specified by [3.1.2.1 Graphic characters](#), is displayed. Because different output devices can respond differently to control characters, programs that use control characters to perform specific functions have an environmental dependency. Each EMIT deals with only one character.

See: [6.1.2310 TYPE](#).

**6.1.1345 ENVIRONMENT?** CORE

“environment-query”

( *c-addr* *u* -- *false* | *i*\**x* *true* )

*c-addr* is the address of a character string and *u* is the string’s character count. *u* may have a value in the range from zero to an implementation-defined maximum which shall not be less than 31. The character string should contain a keyword from [3.2.6 Environmental queries](#) or the optional word sets to be checked for correspondence with an attribute of the present environment. If the system treats the attribute as unknown, the returned flag is *false*; otherwise, the flag is *true* and the *i*\**x* returned is of the type specified in the table for the attribute queried.

See: [A.6.1.1345 ENVIRONMENT?](#).

**6.1.1360 EVALUATE** CORE

$( i * x \ c\text{-}addr \ u \ -- \ j * x )$

Save the current input source specification. Store minus-one (-1) in **SOURCE-ID** if it is present. Make the string described by *c-addr* and *u* both the input source and input buffer, set **>IN** to zero, and interpret. When the parse area is empty, restore the prior input source specification. Other stack effects are due to the words **EVALUATE**d.

**6.1.1370 EXECUTE** CORE

$( i * x \ xt \ -- \ j * x )$

Remove *xt* from the stack and perform the semantics identified by it. Other stack effects are due to the word **EXECUTE**d.

See: [6.1.0070 ' , 6.1.2510 \[ ' \]](#).

**6.1.1380 EXIT** CORE

Interpretation: Interpretation semantics for this word are undefined.

Execution:  $( \ -- \ ) \ ( \ R: \ nest\text{-}sys \ -- \ )$

Return control to the calling definition specified by *nest-sys*. Before executing **EXIT** within a do-loop, a program shall discard the loop-control parameters by executing **UNLOOP**.

See: [3.2.3.3 Return stack, 6.1.2380 UNLOOP, A.6.1.1380 EXIT](#).

**6.1.1540 FILL** CORE

$( c\text{-}addr \ u \ char \ -- \ )$

If *u* is greater than zero, store *char* in each of *u* consecutive characters of memory beginning at *c-addr*.

**6.1.1550 FIND** CORE

$( c\text{-}addr \ -- \ c\text{-}addr \ 0 \ | \ xt \ I \ | \ xt \ -I )$

Find the definition named in the counted string at *c-addr*. If the definition is not found, return *c-addr* and zero. If the definition is found, return its execution token *xt*. If the definition is immediate, also return one (*I*), otherwise also return minus-one (*-I*). For a given string, the values returned by **FIND** while compiling may differ from those returned while not compiling.

See: [3.4.2 Finding definition names, A.6.1.0070 ' , A.6.1.1550 FIND, A.6.1.2033 POSTPONE, A.6.1.2510 \[ ' \]](#).

**6.1.1561**      **FM/MOD**      “f-m-slash-mod”      CORE

(  $d_1 n_1$  --  $n_2 n_3$  )

Divide  $d_1$  by  $n_1$ , giving the floored quotient  $n_3$  and the remainder  $n_2$ . Input and output stack arguments are signed. An ambiguous condition exists if  $n_1$  is zero or if the quotient lies outside the range of a single-cell signed integer.

See: [3.2.2.1 Integer division](#), [6.1.2214 SM/REM](#), [6.1.2370 UM/MOD](#), [A.6.1.1561 FM/MOD](#).

**6.1.1650**      **HERE**      CORE

( -- *addr* )

*addr* is the data-space pointer.

See: [3.3.3.2 Contiguous regions](#).

**6.1.1670**      **HOLD**      CORE

( *char* -- )

Add *char* to the beginning of the pictured numeric output string. An ambiguous condition exists if **HOLD** executes outside of a **<# #>** delimited number conversion.

**6.1.1680**      **I**      CORE

Interpretation: Interpretation semantics for this word are undefined.

Execution: ( --  $n \mid u$  ) ( R: *loop-sys* -- *loop-sys* )

$n \mid u$  is a copy of the current (innermost) loop index. An ambiguous condition exists if the loop control parameters are unavailable.

**6.1.1700**      **IF**      CORE

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: -- *orig* )

Put the location of a new unresolved forward reference *orig* onto the control flow stack. Append the run-time semantics given below to the current definition. The semantics are incomplete until *orig* is resolved, e.g., by **THEN** or **ELSE**.

Run-time: (  $x$  -- )

If all bits of  $x$  are zero, continue execution at the location specified by the resolution of *orig*.

See: [3.2.3.2 Control-flow stack](#), [6.1.1310 ELSE](#), [6.1.2270 THEN](#), [A.6.1.1700 IF](#).

**6.1.1710 IMMEDIATE** CORE

( -- )

Make the most recent definition an immediate word. An ambiguous condition exists if the most recent definition does not have a name or if it was defined as a **SYNONYM**.

See: [15.6.2.2264](#) **SYNONYM** [A.6.1.1710](#) **IMMEDIATE**.

**6.1.1720 INVERT** CORE

(  $x_1$  --  $x_2$  )

Invert all bits of  $x_1$ , giving its logical inverse  $x_2$ .

See: [6.1.1910](#) **NEGATE**, [6.1.0270](#) **0=**, [A.6.1.1720](#) **INVERT**.

**6.1.1730 J** CORE

Interpretation: Interpretation semantics for this word are undefined.

Execution: ( --  $n \mid u$  ) ( R:  $loop\text{-}sys_1 \ loop\text{-}sys_2$  --  $loop\text{-}sys_1 \ loop\text{-}sys_2$  )

$n \mid u$  is a copy of the next-outer loop index. An ambiguous condition exists if the loop control parameters of the next-outer loop,  $loop\text{-}sys_1$ , are unavailable.

See: [A.6.1.1730](#) **J**.

**6.1.1750 KEY** CORE

( -- *char* )

Receive one character *char*, a member of the implementation-defined character set. Keyboard events that do not correspond to such characters are discarded until a valid character is received, and those events are subsequently unavailable.

All standard characters can be received. Characters received by **KEY** are not displayed.

Any standard character returned by **KEY** has the numeric value specified in [3.1.2.1](#) **Graphic characters**. Programs that require the ability to receive control characters have an environmental dependency.

See: [10.6.2.1305](#) **EKEY**, [10.6.2.1307](#) **EKEY?**, [10.6.1.1755](#) **KEY?**, [A.6.1.1750](#) **KEY**.

**6.1.1760 LEAVE** CORE

Interpretation: Interpretation semantics for this word are undefined.

Execution: ( -- ) ( R: *loop-sys* -- )

Discard the current loop control parameters. An ambiguous condition exists if they are unavailable. Continue execution immediately following the innermost syntactically enclosing **DO...LOOP** or **DO...+LOOP**.

See: [3.2.3.3 Return stack](#), [6.1.0140 +LOOP](#), [6.1.1800 LOOP](#), [A.6.1.1760 LEAVE](#).

**6.1.1780 LITERAL** CORE

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( *x* -- )

Append the run-time semantics given below to the current definition.

Run-time: ( -- *x* )

Place *x* on the stack.

See: [A.6.1.1780 LITERAL](#).

**6.1.1800 LOOP** CORE

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: *do-sys* -- )

Append the run-time semantics given below to the current definition. Resolve the destination of all unresolved occurrences of **LEAVE** between the location given by *do-sys* and the next location for a transfer of control, to execute the words following the **LOOP**.

Run-time: ( -- ) ( R: *loop-sys*<sub>1</sub> -- | *loop-sys*<sub>2</sub> )

An ambiguous condition exists if the loop control parameters are unavailable. Add one to the loop index. If the loop index is then equal to the loop limit, discard the loop parameters and continue execution immediately following the loop. Otherwise continue execution at the beginning of the loop.

See: [6.1.1240 DO](#), [6.1.1680 I](#), [6.1.1760 LEAVE](#), [A.6.1.1800 LOOP](#).

**6.1.1805 LSHIFT** CORE “l-shift”

( *x*<sub>1</sub> *u* -- *x*<sub>2</sub> )

Perform a logical left shift of *u* bit-places on *x*<sub>1</sub>, giving *x*<sub>2</sub>. Put zeroes into the least significant bits vacated by the shift. An ambiguous condition exists if *u* is greater than or equal to the number of bits in a cell.

- 6.1.1810**    **M\***    “m-star”    CORE
- $( n_1 n_2 -- d )$   
 $d$  is the signed product of  $n_1$  times  $n_2$ .  
 See: [A.6.1.1810 M\\*](#).
- 6.1.1870**    **MAX**    CORE
- $( n_1 n_2 -- n_3 )$   
 $n_3$  is the greater of  $n_1$  and  $n_2$ .
- 6.1.1880**    **MIN**    CORE
- $( n_1 n_2 -- n_3 )$   
 $n_3$  is the lesser of  $n_1$  and  $n_2$ .
- 6.1.1890**    **MOD**    CORE
- $( n_1 n_2 -- n_3 )$   
 Divide  $n_1$  by  $n_2$ , giving the single-cell remainder  $n_3$ . An ambiguous condition exists if  $n_2$  is zero. If  $n_1$  and  $n_2$  differ in sign, the implementation-defined result returned will be the same as that returned by either the phrase `>R S>D R> FM/MOD DROP` or the phrase `>R S>D R> SM/REM DROP`.  
 See: [3.2.2.1 Integer division](#).
- 6.1.1900**    **MOVE**    CORE
- $( addr_1 addr_2 u -- )$   
 If  $u$  is greater than zero, copy the contents of  $u$  consecutive address units at  $addr_1$  to the  $u$  consecutive address units at  $addr_2$ . After **MOVE** completes, the  $u$  consecutive address units at  $addr_2$  contain exactly what the  $u$  consecutive address units at  $addr_1$  contained before the move.  
 See: [17.6.1.0910 CMOVE](#), [17.6.1.0920 CMOVE>](#), [A.6.1.1900 MOVE](#).
- 6.1.1910**    **NEGATE**    CORE
- $( n_1 -- n_2 )$   
 Negate  $n_1$ , giving its arithmetic inverse  $n_2$ .  
 See: [6.1.1720 INVERT](#), [6.1.0270 0=](#).

**6.1.1980**      **OR**      CORE

$( x_1 x_2 -- x_3 )$

$x_3$  is the bit-by-bit inclusive-or of  $x_1$  with  $x_2$ .

**6.1.1990**      **OVER**      CORE

$( x_1 x_2 -- x_1 x_2 x_1 )$

Place a copy of  $x_1$  on top of the stack.

**6.1.2033**      **POSTPONE**      CORE

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( “*{spaces}name*” -- )

Skip leading space delimiters. Parse *name* delimited by a space. Find *name*. Append the compilation semantics of *name* to the current definition. An ambiguous condition exists if *name* is not found.

See: [3.4.1 Parsing](#), [A.6.1.2033 POSTPONE](#).

**6.1.2050**      **QUIT**      CORE

$( -- ) ( R: i * x -- )$

Empty the return stack, store zero in **SOURCE-ID** if it is present, make the user input device the input source, and enter interpretation state. Do not display a message. Repeat the following:

- Accept a line from the input source into the input buffer, set **>IN** to zero, and interpret.
- Display the implementation-defined system prompt if in interpretation state, all processing has been completed, and no ambiguous condition exists.

See: [3.4 The Forth text interpreter](#).

**6.1.2060**      **R>**      “r-from”      CORE

Interpretation: Interpretation semantics for this word are undefined.

Execution:  $( -- x ) ( R: x -- )$

Move  $x$  from the return stack to the data stack.

See: [3.2.3.3 Return stack](#), [6.1.0580 >R](#), [6.1.2070 R@](#), [6.2.0340 2>R](#), [6.2.0410 2R>](#), [6.2.0415 2R@](#).

**6.1.2165**    **S"**    "s-quote"    CORE

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( "*ccc**<quote>*" -- )

Parse *ccc* delimited by " (double-quote). Append the run-time semantics given below to the current definition.

Run-time: ( -- *c-addr* *u* )

Return *c-addr* and *u* describing a string consisting of the characters *ccc*. A program shall not alter the returned string.

See: [3.4.1 Parsing](#), [6.2.0855 C](#)", [11.6.1.2165 S](#)", [6.2.2266 S\](#)", [A.6.1.2165 S](#)".

**6.1.2170**    **S>D**    "s-to-d"    CORE

( *n* -- *d* )

Convert the number *n* to the double-cell number *d* with the same numerical value.

**6.1.2210**    **SIGN**    CORE

( *n* -- )

If *n* is negative, add a minus sign to the beginning of the pictured numeric output string. An ambiguous condition exists if **SIGN** executes outside of a **<# #>** delimited number conversion.

**6.1.2214**    **SM/REM**    "s-m-slash-rem"    CORE

( *d*<sub>1</sub> *n*<sub>1</sub> -- *n*<sub>2</sub> *n*<sub>3</sub> )

Divide *d*<sub>1</sub> by *n*<sub>1</sub>, giving the symmetric quotient *n*<sub>3</sub> and the remainder *n*<sub>2</sub>. Input and output stack arguments are signed. An ambiguous condition exists if *n*<sub>1</sub> is zero or if the quotient lies outside the range of a single-cell signed integer.

See: [3.2.2.1 Integer division](#), [6.1.1561 FM/MOD](#), [6.1.2370 UM/MOD](#), [A.6.1.2214 SM/REM](#).

**6.1.2216**    **SOURCE**    CORE

( -- *c-addr* *u* )

*c-addr* is the address of, and *u* is the number of characters in, the input buffer.

See: [A.6.1.2216 SOURCE](#).

**6.1.2220**      **SPACE**      CORE

( -- )

Display one space.

**6.1.2230**      **SPACES**      CORE

( n -- )

If *n* is greater than zero, display *n* spaces.

**6.1.2250**      **STATE**      CORE

( -- *a-addr* )

*a-addr* is the address of a cell containing the compilation-state flag. **STATE** is *true* when in compilation state, *false* otherwise. The *true* value in **STATE** is non-zero, but is otherwise implementation-defined. Only the following standard words alter the value in **STATE**: **:** (colon), **;** (semicolon), **ABORT**, **QUIT**, **:NONAME**, **[** (left-bracket), **]** (right-bracket).

Note: A program shall not directly alter the contents of **STATE**.

See: [3.4 The Forth text interpreter](#), [6.1.0450](#) **:**, [6.1.0460](#) **;**, [6.1.0670](#) **ABORT**, [6.1.2050](#) **QUIT**, [6.1.2500](#) **[**, [6.1.2540](#) **]**, [6.2.0455](#) **:NONAME**, [15.6.2.2250](#) **STATE**, [A.6.1.2250](#) **STATE**.

**6.1.2260**      **SWAP**      CORE

( *x<sub>1</sub>* *x<sub>2</sub>* -- *x<sub>2</sub>* *x<sub>1</sub>* )

Exchange the top two stack items.

**6.1.2270**      **THEN**      CORE

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: *orig* -- )

Append the run-time semantics given below to the current definition. Resolve the forward reference *orig* using the location of the appended run-time semantics.

Run-time: ( -- )

Continue execution.

See: [6.1.1310](#) **ELSE**, [6.1.1700](#) **IF**, [A.6.1.2270](#) **THEN**.

- 6.1.2310**      **TYPE**      CORE
- ( *c-addr* *u* -- )
- If *u* is greater than zero, display the character string specified by *c-addr* and *u*.
- When passed a character in a character string whose character-defining bits have a value between hex 20 and 7E inclusive, the corresponding standard character, specified by [3.1.2.1 Graphic characters](#), is displayed. Because different output devices can respond differently to control characters, programs that use control characters to perform specific functions have an environmental dependency.
- See: [6.1.1320 EMIT](#).
- 6.1.2320**      **U.**      “u-dot”      CORE
- ( *u* -- )
- Display *u* in free field format.
- 6.1.2340**      **U<**      “u-less-than”      CORE
- ( *u*<sub>1</sub> *u*<sub>2</sub> -- *flag* )
- flag* is true if and only if *u*<sub>1</sub> is less than *u*<sub>2</sub>.
- See: [6.1.0480 <](#).
- 6.1.2360**      **UM\***      “u-m-star”      CORE
- ( *u*<sub>1</sub> *u*<sub>2</sub> -- *ud* )
- Multiply *u*<sub>1</sub> by *u*<sub>2</sub>, giving the unsigned double-cell product *ud*. All values and arithmetic are unsigned.
- 6.1.2370**      **UM/MOD**      “u-m-slash-mod”      CORE
- ( *ud* *u*<sub>1</sub> -- *u*<sub>2</sub> *u*<sub>3</sub> )
- Divide *ud* by *u*<sub>1</sub>, giving the quotient *u*<sub>3</sub> and the remainder *u*<sub>2</sub>. All values and arithmetic are unsigned. An ambiguous condition exists if *u*<sub>1</sub> is zero or if the quotient lies outside the range of a single-cell unsigned integer.
- See: [3.2.2.1 Integer division](#), [6.1.1561 FM/MOD](#), [6.1.2214 SM/REM](#).

**6.1.2380 UNLOOP** CORE

Interpretation: Interpretation semantics for this word are undefined.

Execution: ( -- ) ( R: *loop-sys* -- )

Discard the loop-control parameters for the current nesting level. An **UNLOOP** is required for each nesting level before the definition may be **EXIT**ed. An ambiguous condition exists if the loop-control parameters are unavailable.

See: [3.2.3.3 Return stack](#), [A.6.1.2380 UNLOOP](#).

**6.1.2390 UNTIL** CORE

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: *dest* -- )

Append the run-time semantics given below to the current definition, resolving the backward reference *dest*.

Run-time: ( *x* -- )

If all bits of *x* are zero, continue execution at the location specified by *dest*.

See: [6.1.0760 BEGIN](#), [A.6.1.2390 UNTIL](#).

**6.1.2410 VARIABLE** CORE

( “*{spaces}name*” -- )

Skip leading space delimiters. Parse *name* delimited by a space. Create a definition for *name* with the execution semantics defined below. Reserve one cell of data space at an aligned address.

*name* is referred to as a “variable”.

*name* Execution: ( -- *a-addr* )

*a-addr* is the address of the reserved cell. A program is responsible for initializing the contents of the reserved cell.

See: [3.4.1 Parsing](#), [A.6.1.2410 VARIABLE](#).

**6.1.2430 WHILE** CORE

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: *dest* -- *orig dest* )

Put the location of a new unresolved forward reference *orig* onto the control flow stack, under the existing *dest*. Append the run-time semantics given below to the current definition. The semantics are incomplete until *orig* and *dest* are resolved (e.g., by [REPEAT](#)).

Run-time: ( *x* -- )

If all bits of *x* are zero, continue execution at the location specified by the resolution of *orig*.

See: [A.6.1.2430 WHILE](#).

**6.1.2450 WORD** CORE

( *char* “*<chars>ccc<char>*” -- *c-addr* )

Skip leading delimiters. Parse characters *ccc* delimited by *char*. An ambiguous condition exists if the length of the parsed string is greater than the implementation-defined length of a counted string.

*c-addr* is the address of a transient region containing the parsed word as a counted string. If the parse area was empty or contained no characters other than the delimiter, the resulting string has a zero length. A program may replace characters within the string.

See: [3.3.3.6 Other transient regions](#), [3.4.1 Parsing](#), [A.6.1.2450 WORD](#).

**6.1.2490 XOR** CORE

“x-or”

( *x*<sub>1</sub> *x*<sub>2</sub> -- *x*<sub>3</sub> )

*x*<sub>3</sub> is the bit-by-bit exclusive-or of *x*<sub>1</sub> with *x*<sub>2</sub>.

**6.1.2500 [** CORE

“left-bracket”

Interpretation: Interpretation semantics for this word are undefined.

Compilation: Perform the execution semantics given below.

Execution: ( -- )

Enter interpretation state. [ is an immediate word.

See: [3.4 The Forth text interpreter](#), [3.4.5 Compilation](#), [6.1.2540 \]](#), [A.6.1.2500 \[](#).

## 6.2 Core extension words

**6.2.0200**     **. (**     “dot-paren”     CORE EXT

Compilation: Perform the execution semantics given below.

Execution: ( “*ccc**<paren>*” -- )

Parse and display *ccc* delimited by ) (right parenthesis). **. (** is an immediate word.

See: [3.4.1 Parsing](#), [6.1.0190 .](#) ", [A.6.2.0200 . \(](#).

**6.2.0210**     **.R**     “dot-r”     CORE EXT

( *n*<sub>1</sub> *n*<sub>2</sub> -- )

Display *n*<sub>1</sub> right aligned in a field *n*<sub>2</sub> characters wide. If the number of characters required to display *n*<sub>1</sub> is greater than *n*<sub>2</sub>, all digits are displayed with no leading spaces in a field as wide as necessary.

See: [A.6.2.0210 .R](#).

**6.2.0260**     **0<>**     “zero-not-equals”     CORE EXT

( *x* -- *flag* )

*flag* is true if and only if *x* is not equal to zero.

**6.2.0280**     **0>**     “zero-greater”     CORE EXT

( *n* -- *flag* )

*flag* is true if and only if *n* is greater than zero.

**6.2.0340**     **2>R**     “two-to-r”     CORE EXT

Interpretation: Interpretation semantics for this word are undefined.

Execution: ( *x*<sub>1</sub> *x*<sub>2</sub> -- ) ( R: -- *x*<sub>1</sub> *x*<sub>2</sub> )

Transfer cell pair *x*<sub>1</sub> *x*<sub>2</sub> to the return stack. Semantically equivalent to [SWAP >R >R](#).

See: [3.2.3.3 Return stack](#), [6.1.0580 >R](#), [6.1.2060 R>](#), [6.1.2070 R@](#), [6.2.0410 2R>](#), [6.2.0415 2R@](#), [A.6.2.0340 2>R](#).

**6.2.0410**     **2R>**     “two-r-from”     CORE EXT

Interpretation: Interpretation semantics for this word are undefined.

Execution: ( --  $x_1 x_2$  ) ( R:  $x_1 x_2$  -- )

Transfer cell pair  $x_1 x_2$  from the return stack. Semantically equivalent to **R> R> SWAP**.

See: **3.2.3.3 Return stack**, **6.1.0580** >R, **6.1.2060** R>, **6.1.2070** R@, **6.2.0340** 2>R, **6.2.0415** 2R@, **A.6.2.0410** 2R>.

**6.2.0415**     **2R@**     “two-r-fetch”     CORE EXT

Interpretation: Interpretation semantics for this word are undefined.

Execution: ( --  $x_1 x_2$  ) ( R:  $x_1 x_2$  --  $x_1 x_2$  )

Copy cell pair  $x_1 x_2$  from the return stack. Semantically equivalent to **R> R> 2DUP >R >R SWAP**.

See: **3.2.3.3 Return stack**, **6.1.0580** >R, **6.1.2060** R>, **6.1.2070** R@, **6.2.0340** 2>R, **6.2.0410** 2R>.

**6.2.0455**     **:NONAME**     “colon-no-name”     CORE EXT

( C: -- *colon-sys* ) ( S: -- *xt* )

Create an execution token *xt*, enter compilation state and start the current definition, producing *colon-sys*. Append the initiation semantics given below to the current definition.

The execution semantics of *xt* will be determined by the words compiled into the body of the definition. This definition can be executed later by using *xt* **EXECUTE**.

If the control-flow stack is implemented using the data stack, *colon-sys* shall be the topmost item on the data stack. See **3.2.3.2 Control-flow stack**.

Initiation: (  $i * x$  --  $i * x$  ) ( R: -- *nest-sys* )

Save implementation-dependent information *nest-sys* about the calling definition. The stack effects  $i * x$  represent arguments to *xt*.

*xt* Execution: (  $i * x$  --  $j * x$  )

Execute the definition specified by *xt*. The stack effects  $i * x$  and  $j * x$  represent arguments to and results from *xt*, respectively.

See: **A.6.2.0455 :NONAME**.

**6.2.0500**    **<>**    “not-equals”    CORE EXT

(  $x_1$   $x_2$  -- *flag* )

*flag* is true if and only if  $x_1$  is not bit-for-bit the same as  $x_2$ .

**6.2.0620**    **?DO**    “question-do”    CORE EXT

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: -- *do-sys* )

Put *do-sys* onto the control-flow stack. Append the run-time semantics given below to the current definition. The semantics are incomplete until resolved by a consumer of *do-sys* such as **LOOP**.

Run-time: (  $n_1$  |  $u_1$   $n_2$  |  $u_2$  -- ) ( R: -- *loop-sys* )

If  $n_1$  |  $u_1$  is equal to  $n_2$  |  $u_2$ , continue execution at the location given by the consumer of *do-sys*. Otherwise set up loop control parameters with index  $n_2$  |  $u_2$  and limit  $n_1$  |  $u_1$  and continue executing immediately following **?DO**. Anything already on the return stack becomes unavailable until the loop control parameters are discarded. An ambiguous condition exists if  $n_1$  |  $u_1$  and  $n_2$  |  $u_2$  are not both of the same type.

See: **3.2.3.2 Control-flow stack**, **6.1.0140 +LOOP**, **6.1.1240 DO**, **6.1.1680 I**, **6.1.1760 LEAVE**, **6.1.1800 LOOP**, **6.1.2380 UNLOOP**, **A.6.2.0620 ?DO**.

x:reset

**6.2.0698**    **ACTION-OF**    CORE EXT  
X:deferred

Interpretation: ( “*spaces**name*” -- *xt* )

Skip leading spaces and parse *name* delimited by a space. *xt* is the execution token that *name* is set to execute. An ambiguous condition exists if *name* was not defined by **DEFER**, or if the *name* has not been set to execute an *xt*.

Compilation: ( “*spaces**name*” -- )

Skip leading spaces and parse *name* delimited by a space. Append the run-time semantics given below to the current definition. An ambiguous condition exists if *name* was not defined by **DEFER**.

Run-time: ( -- *xt* )

*xt* is the execution token that *name* is set to execute. An ambiguous condition exists if *name* has not been set to execute an *xt*.

An ambiguous condition exists if **POSTPONE**, **[COMPILE]**, **[']** or **'** is applied to **ACTION-OF**.

See: **6.2.1173 DEFER**, **6.2.1175 DEFER!**, **6.2.1177 DEFER@**, **6.2.1725 IS**.

**6.2.0700 AGAIN** CORE EXT

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: *dest* -- )

Append the run-time semantics given below to the current definition, resolving the backward reference *dest*.

Run-time: ( -- )

Continue execution at the location specified by *dest*. If no other control flow words are used, any program code after **AGAIN** will not be executed.

See: [6.1.0760 BEGIN](#), [A.6.2.0700 AGAIN](#).

**6.2.0825 BUFFER:** “buffer-colon” CORE EXT

x:reset

\*buffer

( *u* “*{spaces}name*” -- )

Skip leading space delimiters. Parse *name* delimited by a space. Create a definition for *name*, with the execution semantics defined below. Reserve *u* address units at an aligned address. Contiguity of this region with any other region is undefined.

*name* Execution: ( -- *a-addr* )

*a-addr* is the address of the space reserved by **BUFFER:** when it defined *name*. The program is responsible for initializing the contents.

See: [A.6.2.0825 BUFFER:](#).

**6.2.0855 C"** “c-quote” CORE EXT

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( “*ccc{quote}*” -- )

Parse *ccc* delimited by " (double-quote) and append the run-time semantics given below to the current definition.

Run-time: ( -- *c-addr* )

Return *c-addr*, a counted string consisting of the characters *ccc*. A program shall not alter the returned string.

See: [3.4.1 Parsing](#), [6.1.2165 S](#)", [11.6.1.2165 S](#)", [A.6.2.0855 C"](#).

**6.2.0873 CASE** CORE EXT

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: -- *case-sys* )

Mark the start of the **CASE...OF...ENDOF...ENDCASE** structure. Append the run-time semantics given below to the current definition.

Run-time: ( -- )

Continue execution.

See: [6.2.1342 ENDCASE](#), [6.2.1343 ENDOF](#), [6.2.1950 OF](#), [A.6.2.0873 CASE](#).

**6.2.0945 COMPILER,** “compile-comma” CORE EXT

Interpretation: Interpretation semantics for this word are undefined.

Execution: ( *xt* -- )

Append the execution semantics of the definition represented by *xt* to the execution semantics of the current definition.

See: [A.6.2.0945 COMPILER,](#) .

x:reset

**6.2.1173 DEFER** CORE EXT  
X:deferred

( “*{spaces}name*” -- )

Skip leading space delimiters. Parse *name* delimited by a space. Create a definition for *name* with the execution semantics defined below.

*name* Execution: ( *i*\**x* -- *j*\**x* )

Execute the *xt* that *name* is set to execute. An ambiguous condition exists if *name* has not been set to execute an *xt*.

See: [6.2.0698 ACTION-OF](#), [6.2.1175 DEFER!](#), [6.2.1177 DEFER@](#), [6.2.1725 IS](#).

x:reset

**6.2.1175 DEFER!** “defer-store” CORE EXT  
X:deferred

( *xt*<sub>2</sub> *xt*<sub>1</sub> -- )

Set the word *xt*<sub>1</sub> to execute *xt*<sub>2</sub>. An ambiguous condition exists if *xt*<sub>1</sub> is not for a word defined by **DEFER**.

See: [6.2.0698 ACTION-OF](#), [6.2.1173 DEFER](#), [6.2.1177 DEFER@](#), [6.2.1725 IS](#).

x:reset

**6.2.1485 FALSE** CORE EXT

( -- *false* )

Return a *false* flag.

See: [3.1.3.1 Flags](#)

**6.2.1660 HEX** CORE EXT

( -- )

Set contents of **BASE** to sixteen.

x:reset

**6.2.1675 HOLDS** CORE EXT

X:xchar

( *c-addr u* -- )

Adds the string represented by *c-addr u* to the pictured numeric output string. An ambiguous condition exists if **HOLDS** executes outside of a **<# #>** delimited number conversion.

See: [6.1.1670 HOLD](#).

x:reset

**6.2.1725 IS** CORE EXT

X:deferred

Interpretation: ( *xt* “*{spaces}name*” -- )

Skip leading spaces and parse *name* delimited by a space. Set *name* to execute *xt*.

An ambiguous condition exists if *name* was not defined by **DEFER**.

Compilation: ( “*{spaces}name*” -- )

Skip leading spaces and parse *name* delimited by a space. Append the run-time semantics given below to the current definition. An ambiguous condition exists if *name* was not defined by **DEFER**.

Run-time: ( *xt* -- )

Set *name* to execute *xt*.

An ambiguous condition exists if **POSTPONE**, **[COMPILE]**, **[']** or **'** is applied to **IS**.

See: [6.2.0698 ACTION-OF](#), [6.2.1173 DEFER](#), [6.2.1175 DEFER!](#), [6.2.1177 DEFER@](#).

**6.2.1850      MARKER      CORE EXT**

( “*{spaces}**name*” -- )

Skip leading space delimiters. Parse *name* delimited by a space. Create a definition for *name* with the execution semantics defined below.

*name* Execution: ( -- )

Restore all dictionary allocation and search order pointers to the state they had just prior to the definition of *name*. Remove the definition of *name* and all subsequent definitions. Restoration of any structures still existing that could refer to deleted definitions or deallocated data space is not necessarily provided. No other contextual information such as numeric base is affected.

See: [3.4.1 Parsing](#), [15.6.2.1580 FORGET](#), [A.6.2.1850 MARKER](#).

**6.2.1930      NIP      CORE EXT**

( *x*<sub>1</sub> *x*<sub>2</sub> -- *x*<sub>2</sub> )

Drop the first item below the top of stack.

**6.2.1950      OF      CORE EXT**

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: -- *of-sys* )

Put *of-sys* onto the control flow stack. Append the run-time semantics given below to the current definition. The semantics are incomplete until resolved by a consumer of *of-sys* such as [ENDOF](#).

Run-time: ( *x*<sub>1</sub> *x*<sub>2</sub> -- | *x*<sub>1</sub> )

If the two values on the stack are not equal, discard the top value and continue execution at the location specified by the consumer of *of-sys*, e.g., following the next [ENDOF](#). Otherwise, discard both values and continue execution in line.

See: [6.2.0873 CASE](#), [6.2.1342 ENDCASE](#), [6.2.1343 ENDOF](#), [A.6.2.1950 OF](#).

**6.2.2000      PAD      CORE EXT**

( -- *c-addr* )

*c-addr* is the address of a transient region that can be used to hold data for intermediate processing.

See: [3.3.3.6 Other transient regions](#), [A.6.2.2000 PAD](#).

**6.2.2008      PARSE      CORE EXT**

( *char* “*ccc*<*char*>” -- *c-addr* *u* )

Parse *ccc* delimited by the delimiter *char*.

*c-addr* is the address (within the input buffer) and *u* is the length of the parsed string. If the parse area was empty, the resulting string has a zero length.

See: [3.4.1 Parsing](#), [A.6.2.2008 PARSE](#).

x:reset

**6.2.2020      PARSE-NAME      CORE EXT**  
X:parse-name

( “<*spaces*>*name*<*space*>” -- *c-addr* *u* )

Skip leading space delimiters. Parse *name* delimited by a space.

*c-addr* is the address of the selected string within the input buffer and *u* is its length in characters. If the parse area is empty or contains only white space, the resulting string has length zero.

**6.2.2030      PICK      CORE EXT**

( *x<sub>u</sub> . . . x<sub>1</sub> x<sub>0</sub> u* -- *x<sub>u</sub> . . . x<sub>1</sub> x<sub>0</sub> x<sub>u</sub>* )

Remove *u*. Copy the *x<sub>u</sub>* to the top of the stack. An ambiguous condition exists if there are less than *u+2* items on the stack before **PICK** is executed.

See: [A.6.2.2030 PICK](#).

**6.2.2125      REFILL      CORE EXT**

( -- *flag* )

Attempt to fill the input buffer from the input source, returning a true flag if successful.

When the input source is the user input device, attempt to receive input into the terminal input buffer. If successful, make the result the input buffer, set **>IN** to zero, and return *true*. Receipt of a line containing no characters is considered successful. If there is no input available from the current input source, return *false*.

When the input source is a string from **EVALUATE**, return *false* and perform no other action.

See: [7.6.2.2125 REFILL](#), [11.6.2.2125 REFILL](#), [A.6.2.2125 REFILL](#).

**6.2.2148      RESTORE-INPUT      CORE EXT**

(  $x_n \dots x_1 n -- flag$  )

Attempt to restore the input source specification to the state described by  $x_1$  through  $x_n$ . *flag* is true if the input source specification cannot be so restored.

An ambiguous condition exists if the input source represented by the arguments is not the same as the current input source.

See: [15.6.2.1908](#) N>R, [15.6.2.1940](#) NR>, [A.6.2.2182](#) SAVE-INPUT.

**6.2.2150      ROLL      CORE EXT**

(  $x_u x_{u-1} \dots x_0 u -- x_{u-1} \dots x_0 x_u$  )

Remove  $u$ . Rotate  $u+1$  items on the top of the stack. An ambiguous condition exists if there are less than  $u+2$  items on the stack before **ROLL** is executed.

See: [A.6.2.2150](#) ROLL.

x:reset

**6.2.2266      S\ "      "s-backslash-quote"      CORE EXT**  
X:escaped-strings

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( "*ccc**<quote>*" -- )

Parse *ccc* delimited by " (double-quote), using the translation rules below. Append the run-time semantics given below to the current definition.

Translation rules: Characters are processed one at a time and appended to the compiled string. If the character is a '\ ' character it is processed by parsing and substituting one or more characters as follows, where the character after the backslash is case sensitive:

\a	BEL	(alert,	ASCII 7)
\b	BS	(backspace,	ASCII 8)
\e	ESC	(escape,	ASCII 27)
\f	FF	(form feed,	ASCII 12)
\l	LF	(line feed,	ASCII 10)
\m	CR/LF	pair	(ASCII 13, 10)
\n	newline	(implementation dependent , e.g., CR/LF, CR, LF, LF/CR)	
\q	double-quote		(ASCII 34)
\r	CR	(carriage return,	ASCII 13)
\t	HT	(horizontal tab,	ASCII 9)
\v	VT	(vertical tab,	ASCII 11)
\z	NUL	(no character,	ASCII 0)
\"	double-quote		(ASCII 34)
\x	<i>&lt;hexdigit&gt;</i> <i>&lt;hexdigit&gt;</i>		

The resulting character is the conversion of these two hexadecimal digits. An ambiguous conditions exists if \x is not followed by two hexadecimal characters.

\\	backslash itself	(ASCII 92)
----	------------------	------------

An ambiguous condition exists if a \ is placed before any character, other than those defined in here.

Run-time: ( -- *c-addr* *u* )

Return *c-addr* and *u* describing a string consisting of the translation of the characters *ccc*. A program shall not alter the returned string.

See: [3.4.1 Parsing](#), [6.2.0855 C](#)", [11.6.1.2165 S](#)", [A.6.1.2165 S](#)".

**6.2.2182**      **SAVE-INPUT**      CORE EXT

( --  $x_n \dots x_1 n$  )

$x_1$  through  $x_n$  describe the current state of the input source specification for later use by [RESTORE-INPUT](#).

See: [15.6.2.1908 N>R](#), [15.6.2.1940 NR>](#), [A.6.2.2182 SAVE-INPUT](#).

**6.2.2218**      **SOURCE-ID**      "source-i-d"      CORE EXT

( -- 0 | -1 )

Identifies the input source as follows:

<b>SOURCE-ID</b>	Input source
-1	String (via <a href="#">EVALUATE</a> )
0	User input device

See: [11.6.1.2218 SOURCE-ID](#).

**6.2.2295**      **TO**      CORE EXT

Interpretation: ( *i* \* *x* "*{spaces}name*" -- )

Skip leading spaces and parse *name* delimited by a space. Perform the "TO *name* run-time" semantics given in the definition for the defining word of *name*. An ambiguous condition exists if *name* was not defined by a word with "TO *name* run-time" semantics.

Compilation: ( "*{spaces}name*" -- )

Skip leading spaces and parse *name* delimited by a space. Append the "TO *name* run-time" semantics given in the definition for the defining word of *name* to the current definition. An ambiguous condition exists if *name* was not defined by a word with "TO *name* run-time" semantics.

Note: An ambiguous condition exists if any of [POSTPONE](#), [\[COMPILE\]](#), ' or [ ' ] are applied to **TO**.

See: [6.2.2405 VALUE](#), [8.6.2.0435 2VALUE](#), [12.6.2.1628 FVALUE](#), [13.6.1.0086 \(LOCAL\)](#), [A.6.2.2295 TO](#).

- 6.2.2298**     **TRUE**     CORE EXT
- ( -- *true* )
- Return a *true* flag, a single-cell value with all bits set.
- See: [3.1.3.1 Flags](#), [A.6.2.2298 TRUE](#).
- 6.2.2300**     **TUCK**     CORE EXT
- (  $x_1 x_2$  --  $x_2 x_1 x_2$  )
- Copy the first (top) stack item below the second stack item.
- 6.2.2330**     **U.R**     “u-dot-r”     CORE EXT
- (  $u n$  -- )
- Display  $u$  right aligned in a field  $n$  characters wide. If the number of characters required to display  $u$  is greater than  $n$ , all digits are displayed with no leading spaces in a field as wide as necessary.
- 6.2.2350**     **U>**     “u-greater-than”     CORE EXT
- (  $u_1 u_2$  -- *flag* )
- flag* is true if and only if  $u_1$  is greater than  $u_2$ .
- See: [6.1.0540 >](#).
- 6.2.2395**     **UNUSED**     CORE EXT
- ( --  $u$  )
- $u$  is the amount of space remaining in the region addressed by [HERE](#), in address units.
- 6.2.2405**     **VALUE**     CORE EXT
- (  $x$  “ $\langle spaces \rangle name$ ” -- )
- Skip leading space delimiters. Parse *name* delimited by a space. Create a definition for *name* with the execution semantics defined below, with an initial value equal to  $x$ .
- name* is referred to as a “value”.
- name* Execution: ( --  $x$  )
- Place  $x$  on the stack. The value of  $x$  is that given when *name* was created, until the phrase  $x$  **TO** *name* is executed, causing a new value of  $x$  to be assigned to *name*.

**TO** *name* Run-time: ( *x* -- )

Assign the value *x* to *name*.

See: [3.4.1 Parsing](#), [6.2.2295 TO](#), [A.6.2.2405 VALUE](#).

**6.2.2440 WITHIN** CORE EXT

( *n*<sub>1</sub> | *u*<sub>1</sub> *n*<sub>2</sub> | *u*<sub>2</sub> *n*<sub>3</sub> | *u*<sub>3</sub> -- *flag* )

Perform a comparison of a test value *n*<sub>1</sub> | *u*<sub>1</sub> with a lower limit *n*<sub>2</sub> | *u*<sub>2</sub> and an upper limit *n*<sub>3</sub> | *u*<sub>3</sub>, returning *true* if either (*n*<sub>2</sub> | *u*<sub>2</sub> < *n*<sub>3</sub> | *u*<sub>3</sub> and (*n*<sub>2</sub> | *u*<sub>2</sub> <= *n*<sub>1</sub> | *u*<sub>1</sub> and *n*<sub>1</sub> | *u*<sub>1</sub> < *n*<sub>3</sub> | *u*<sub>3</sub>) or (*n*<sub>2</sub> | *u*<sub>2</sub> > *n*<sub>3</sub> | *u*<sub>3</sub> and (*n*<sub>2</sub> | *u*<sub>2</sub> <= *n*<sub>1</sub> | *u*<sub>1</sub> or *n*<sub>1</sub> | *u*<sub>1</sub> < *n*<sub>3</sub> | *u*<sub>3</sub>) is true, returning *false* otherwise. An ambiguous condition exists *n*<sub>1</sub> | *u*<sub>1</sub>, *n*<sub>2</sub> | *u*<sub>2</sub>, and *n*<sub>3</sub> | *u*<sub>3</sub> are not all the same type.

See: [A.6.2.2440 WITHIN](#).

**6.2.2530 [COMPILE]** CORE EXT

“bracket-compile”

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( “*{spaces}**name*” -- )

Skip leading space delimiters. Parse *name* delimited by a space. Find *name*. If *name* has other than default compilation semantics, append them to the current definition; otherwise append the execution semantics of *name*. An ambiguous condition exists if *name* is not found.

Note: This word is obsolescent and is included as a concession to existing implementations.

See: [3.4.1 Parsing](#), [A.6.2.2530 \[COMPILE\]](#).

**6.2.2535 \** CORE EXT

“backslash”

Compilation: Perform the execution semantics given below.

Execution: ( “*ccc**eol*” -- )

Parse and discard the remainder of the parse area. \ is an immediate word.

See: [7.6.2.2535 \](#), [A.6.2.2535 \](#).

## 7 The optional Block word set

### 7.1 Introduction

### 7.2 Additional terms

**block:** 1024 characters of data on mass storage, designated by a block number.

**block buffer:** A block-sized region of data space where a block is made temporarily available for use. The current block buffer is the block buffer most recently accessed by **BLOCK**, **BUFFER**, **LOAD**, **LIST**, or **THRU**.

### 7.3 Additional usage requirements

#### 7.3.1 Data space

A program may access memory within a valid block buffer.

See: [3.3.3 Data space](#).

#### 7.3.2 Block buffer regions

The address of a block buffer returned by **BLOCK** or **BUFFER** is transient. A call to **BLOCK** or **BUFFER** may render a previously-obtained block-buffer address invalid, as may a call to any word that:

- parses;
- displays characters on the user output device, such as **TYPE** or **EMIT**;
- controls the user output device, such as **CR** or **AT-XY**;
- receives or tests for the presence of characters from the user input device such as **ACCEPT** or **KEY**;
- waits for a condition or event, such as **MS** or **EKEY**;
- manages the block buffers, such as **FLUSH**, **SAVE-BUFFERS**, or **EMPTY-BUFFERS**;
- performs any operation on a file or file-name directory that implies I/O, such as **REFILL** or any word that returns an *ior*;
- implicitly performs I/O, such as text interpreter nesting and un-nesting when files are being used (including un-nesting implied by **THROW**).

If the input source is a block, these restrictions also apply to the address returned by **SOURCE**. Block buffers are uniquely assigned to blocks.

See [A.7.3.2 Block buffer regions](#).

#### 7.3.3 Parsing

The Block word set implements an alternative input source for the text interpreter. When the input source is a block, **BLK** shall contain the non-zero block number and the input buffer is the 1024-character buffer containing that block.

A block is conventionally displayed as 16 lines of 64 characters.

A program may switch the input source to a block by using **LOAD** or **THRU**. Input sources may be nested using **LOAD** and **EVALUATE** in any order.

A program may reposition the parse area within a block by manipulating **>IN**. More extensive repositioning can be accomplished using **SAVE-INPUT** and **RESTORE-INPUT**.

See: [3.4.1 Parsing](#).

### 7.3.4 Possible action on an ambiguous condition

See: [3.4.4 Possible actions on an ambiguous condition](#).

- A system with the Block word set may set interpretation state and interpret a block.

## 7.4 Additional documentation requirements

### 7.4.1 System documentation

#### 7.4.1.1 Implementation-defined options

- the format used for display by [7.6.2.1770 LIST](#) (if implemented);
- the length of a line affected by [7.6.2.2535 \](#) (if implemented).

#### 7.4.1.2 Ambiguous conditions

- Correct block read was not possible;
- I/O exception in block transfer;
- Invalid block number ([7.6.1.0800 BLOCK](#), [7.6.1.0820 BUFFER](#), [7.6.1.1790 LOAD](#));
- A program directly alters the contents of [7.6.1.0790 BLK](#);
- No current block buffer for [7.6.1.2400 UPDATE](#).

#### 7.4.1.3 Other system documentation

- any restrictions a multiprogramming system places on the use of buffer addresses;
- the number of blocks available for source text and data.

### 7.4.2 Program documentation

- the number of blocks required by the program.

## 7.5 Compliance and labeling

### 7.5.1 Forth-2012 systems

The phrase “Providing the Block word set” shall be appended to the label of any Standard System that provides all of the Block word set.

The phrase “Providing *name(s)* from the Block Extensions word set” shall be appended to the label of any Standard System that provides portions of the Block Extensions word set.

The phrase “Providing the Block Extensions word set” shall be appended to the label of any Standard System that provides all of the Block and Block Extensions word sets.

### 7.5.2 Forth-2012 programs

The phrase “Requiring the Block word set” shall be appended to the label of Standard Programs that require the system to provide the Block word set.

The phrase “Requiring *name(s)* from the Block Extensions word set” shall be appended to the label of Standard Programs that require the system to provide portions of the Block Extensions word set.

The phrase “Requiring the Block Extensions word set” shall be appended to the label of Standard Programs that require the system to provide all of the Block and Block Extensions word sets.

## 7.6 Glossary

### 7.6.1 Block words

**7.6.1.0790**     **BLK**     “b-l-k”     **BLOCK**

( -- *a-addr* )

*a-addr* is the address of a cell containing zero or the number of the mass-storage block being interpreted. If **BLK** contains zero, the input source is not a block and can be identified by **SOURCE-ID**, if **SOURCE-ID** is available. An ambiguous condition exists if a program directly alters the contents of **BLK**.

See: [7.3.2 Block buffer regions](#).

**7.6.1.0800**     **BLOCK**     **BLOCK**

( *u* -- *a-addr* )

*a-addr* is the address of the first character of the block buffer assigned to mass-storage block *u*. An ambiguous condition exists if *u* is not an available block number.

If block *u* is already in a block buffer, *a-addr* is the address of that block buffer.

If block *u* is not already in memory and there is an unassigned block buffer, transfer block *u* from mass storage to an unassigned block buffer. *a-addr* is the address of that block buffer.

If block *u* is not already in memory and there are no unassigned block buffers, unassign a block buffer. If the block in that buffer has been **UPDATED**, transfer the block to mass storage and transfer block *u* from mass storage into that buffer. *a-addr* is the address of that block buffer.

At the conclusion of the operation, the block buffer pointed to by *a-addr* is the current block buffer and is assigned to *u*.

**7.6.1.0820 BUFFER** BLOCK

$( u -- a-addr )$

*a-addr* is the address of the first character of the block buffer assigned to block *u*. The contents of the block are unspecified. An ambiguous condition exists if *u* is not an available block number.

If block *u* is already in a block buffer, *a-addr* is the address of that block buffer.

If block *u* is not already in memory and there is an unassigned buffer, *a-addr* is the address of that block buffer.

If block *u* is not already in memory and there are no unassigned block buffers, unassign a block buffer. If the block in that buffer has been **UPDATE**d, transfer the block to mass storage. *a-addr* is the address of that block buffer.

At the conclusion of the operation, the block buffer pointed to by *a-addr* is the current block buffer and is assigned to *u*.

See: [7.6.1.0800 BLOCK](#).

**7.6.1.1360 EVALUATE** BLOCK

Extend the semantics of [6.1.1360 EVALUATE](#) to include: Store zero in **BLK**.

**7.6.1.1559 FLUSH** BLOCK

$( -- )$

Perform the function of **SAVE-BUFFERS**, then unassign all block buffers.

**7.6.1.1790 LOAD** BLOCK

$( i * x u -- j * x )$

Save the current input-source specification. Store *u* in **BLK** (thus making block *u* the input source and setting the input buffer to encompass its contents), set **>IN** to zero, and interpret. When the parse area is exhausted, restore the prior input source specification. Other stack effects are due to the words **LOAD**ed.

An ambiguous condition exists if *u* is zero or is not a valid block number.

See: [3.4 The Forth text interpreter](#).

**7.6.1.2180 SAVE-BUFFERS** BLOCK

( -- )

Transfer the contents of each **UPDATED** block buffer to mass storage. Mark all buffers as unmodified.

**7.6.1.2400 UPDATE** BLOCK

( -- )

Mark the current block buffer as modified. An ambiguous condition exists if there is no current block buffer.

**UPDATE** does not immediately cause I/O.

See: [7.6.1.0800 BLOCK](#), [7.6.1.0820 BUFFER](#), [7.6.1.1559 FLUSH](#),  
[7.6.1.2180 SAVE-BUFFERS](#).

## 7.6.2 Block extension words

**7.6.2.1330 EMPTY-BUFFERS** BLOCK EXT

( -- )

Unassign all block buffers. Do not transfer the contents of any **UPDATED** block buffer to mass storage.

See: [7.6.1.0800 BLOCK](#).

**7.6.2.1770 LIST** BLOCK EXT

( *u* -- )

Display block *u* in an implementation-defined format. Store *u* in **SCR**.

See: [7.6.1.0800 BLOCK](#).

**7.6.2.2125 REFILL** BLOCK EXT

( -- *flag* )

Extend the execution semantics of [6.2.2125 REFILL](#) with the following:

When the input source is a block, make the next block the input source and current input buffer by adding one to the value of **BLK** and setting **>IN** to zero. Return *true* if the new value of **BLK** is a valid block number, otherwise *false*.

See: [6.2.2125 REFILL](#), [11.6.2.2125 REFILL](#).

**7.6.2.2190**    **SCR**    “s-c-r”    BLOCK EXT

( -- *a-addr* )

*a-addr* is the address of a cell containing the block number of the block most recently **LIST**ed.

See: **A.7.6.2.2190** SCR.

**7.6.2.2280**    **THRU**    BLOCK EXT

( *i\*x u<sub>1</sub> u<sub>2</sub> -- j\*x* )

**LOAD** the mass storage blocks numbered *u<sub>1</sub>* through *u<sub>2</sub>* in sequence. Other stack effects are due to the words **LOAD**ed.

**7.6.2.2535**    **\**    “backslash”    BLOCK EXT

Extend the semantics of **6.2.2535** **\** to be:

Compilation: Perform the execution semantics given below.

Execution: ( “*ccc*⟨*eol*⟩” -- )

If **BLK** contains zero, parse and discard the remainder of the parse area; otherwise parse and discard the portion of the parse area corresponding to the remainder of the current line. **\** is an immediate word.

## 8 The optional Double-Number word set

### 8.1 Introduction

Sixteen-bit Forth systems often use double-length numbers. However, many Forths on small embedded systems do not, and many users of Forth on systems with a cell size of 32 bits or more find that the use of double-length numbers is much diminished. Therefore, the words that manipulate double-length entities have been placed in this optional word set.

### 8.2 Additional terms and notation

None.

### 8.3 Additional usage requirements

#### 8.3.1 Text interpreter input number conversion

When the text interpreter processes a number, except a *<num>*, that is immediately followed by a decimal point and is not found as a definition name, the text interpreter shall convert it to a double-cell number.

For example, entering **DECIMAL** 1234 leaves the single-cell number 1234 on the stack, and entering **DECIMAL** 1234 . leaves the double-cell number 1234 0 on the stack.

See: [3.4.1.3 Text interpreter input number conversion](#).

### 8.4 Additional documentation requirements

#### 8.4.1 System documentation

##### 8.4.1.1 Implementation-defined options

- no additional requirements.

##### 8.4.1.2 Ambiguous conditions

- *d* outside range of *n* in [8.6.1.1140 D>S](#).

##### 8.4.1.3 Other system documentation

- no additional requirements.

#### 8.4.2 Program documentation

- no additional requirements.

### 8.5 Compliance and labeling

#### 8.5.1 Forth-2012 systems

The phrase “Providing the Double-Number word set” shall be appended to the label of any Standard System that provides all of the Double-Number word set.

The phrase “Providing *name(s)* from the Double-Number Extensions word set” shall be appended to the label of any Standard System that provides portions of the Double-Number Extensions word set.

The phrase “Providing the Double-Number Extensions word set” shall be appended to the label of any Standard System that provides all of the Double-Number and Double-Number Extensions word sets.

### 8.5.2 Forth-2012 programs

The phrase “Requiring the Double-Number word set” shall be appended to the label of Standard Programs that require the system to provide the Double-Number word set.

The phrase “Requiring *name(s)* from the Double-Number Extensions word set” shall be appended to the label of Standard Programs that require the system to provide portions of the Double-Number Extensions word set.

The phrase “Requiring the Double-Number Extensions word set” shall be appended to the label of Standard Programs that require the system to provide all of the Double-Number and Double-Number Extensions word sets.

## 8.6 Glossary

### 8.6.1 Double-Number words

**8.6.1.0360**    **2CONSTANT**    “two-constant”    DOUBLE

$(x_1 x_2 \text{ “}\langle\text{spaces}\rangle\text{name” } -- )$

Skip leading space delimiters. Parse *name* delimited by a space. Create a definition for *name* with the execution semantics defined below.

*name* is referred to as a “two-constant”.

*name* Execution:  $( -- x_1 x_2 )$

Place cell pair  $x_1 x_2$  on the stack.

See: [3.4.1 Parsing](#), [A.8.6.1.0360 2CONSTANT](#).

**8.6.1.0390**    **2LITERAL**    “two-literal”    DOUBLE

Interpretation: Interpretation semantics for this word are undefined.

Compilation:  $( x_1 x_2 -- )$

Append the run-time semantics below to the current definition.

Run-time:  $( -- x_1 x_2 )$

Place cell pair  $x_1 x_2$  on the stack.

See: [A.8.6.1.0390 2LITERAL](#).

**8.6.1.0440**    **2VARIABLE**    “two-variable”    DOUBLE

( “*{spaces}**name*” -- )

Skip leading space delimiters. Parse *name* delimited by a space. Create a definition for *name* with the execution semantics defined below. Reserve two consecutive cells of data space.

*name* is referred to as a “two-variable”.

*name* Execution: ( -- *a-addr* )

*a-addr* is the address of the first (lowest address) cell of two consecutive cells in data space reserved by **2VARIABLE** when it defined *name*. A program is responsible for initializing the contents.

See: [3.4.1 Parsing](#), [6.1.2410 VARIABLE](#), [A.8.6.1.0440 2VARIABLE](#).

**8.6.1.1040**    **D+**    “d-plus”    DOUBLE

( *d*<sub>1</sub> | *ud*<sub>1</sub> *d*<sub>2</sub> | *ud*<sub>2</sub> -- *d*<sub>3</sub> | *ud*<sub>3</sub> )

Add *d*<sub>2</sub> | *ud*<sub>2</sub> to *d*<sub>1</sub> | *ud*<sub>1</sub>, giving the sum *d*<sub>3</sub> | *ud*<sub>3</sub>.

**8.6.1.1050**    **D-**    “d-minus”    DOUBLE

( *d*<sub>1</sub> | *ud*<sub>1</sub> *d*<sub>2</sub> | *ud*<sub>2</sub> -- *d*<sub>3</sub> | *ud*<sub>3</sub> )

Subtract *d*<sub>2</sub> | *ud*<sub>2</sub> from *d*<sub>1</sub> | *ud*<sub>1</sub>, giving the difference *d*<sub>3</sub> | *ud*<sub>3</sub>.

**8.6.1.1060**    **D.**    “d-dot”    DOUBLE

( *d* -- )

Display *d* in free field format.

**8.6.1.1070**    **D.R**    “d-dot-r”    DOUBLE

( *d n* -- )

Display *d* right aligned in a field *n* characters wide. If the number of characters required to display *d* is greater than *n*, all digits are displayed with no leading spaces in a field as wide as necessary.

See: [A.8.6.1.1070 D.R](#).

<b>8.6.1.1075</b>	<b>D0&lt;</b>	“d-zero-less”	DOUBLE
	$( d -- flag )$		
	<i>flag</i> is true if and only if <i>d</i> is less than zero.		
<b>8.6.1.1080</b>	<b>D0=</b>	“d-zero-equals”	DOUBLE
	$( xd -- flag )$		
	<i>flag</i> is true if and only if <i>xd</i> is equal to zero.		
<b>8.6.1.1090</b>	<b>D2*</b>	“d-two-star”	DOUBLE
	$( xd_1 -- xd_2 )$		
	<i>xd<sub>2</sub></i> is the result of shifting <i>xd<sub>1</sub></i> one bit toward the most-significant bit, filling the vacated least-significant bit with zero.		
<b>8.6.1.1100</b>	<b>D2/</b>	“d-two-slash”	DOUBLE
	$( xd_1 -- xd_2 )$		
	<i>xd<sub>2</sub></i> is the result of shifting <i>xd<sub>1</sub></i> one bit toward the least-significant bit, leaving the most-significant bit unchanged.		
<b>8.6.1.1110</b>	<b>D&lt;</b>	“d-less-than”	DOUBLE
	$( d_1 d_2 -- flag )$		
	<i>flag</i> is true if and only if <i>d<sub>1</sub></i> is less than <i>d<sub>2</sub></i> .		
<b>8.6.1.1120</b>	<b>D=</b>	“d-equals”	DOUBLE
	$( xd_1 xd_2 -- flag )$		
	<i>flag</i> is true if and only if <i>xd<sub>1</sub></i> is bit-for-bit the same as <i>xd<sub>2</sub></i> .		
<b>8.6.1.1140</b>	<b>D&gt;S</b>	“d-to-s”	DOUBLE
	$( d -- n )$		
	<i>n</i> is the equivalent of <i>d</i> . An ambiguous condition exists if <i>d</i> lies outside the range of a signed single-cell number.		

See: [A.8.6.1.1140 D>S](#).

<b>8.6.1.1160</b>	<b>DABS</b>	“d-abs”	DOUBLE
	$(d \text{ -- } ud)$		
	$ud$ is the absolute value of $d$ .		
<b>8.6.1.1210</b>	<b>DMAX</b>	“d-max”	DOUBLE
	$(d_1 d_2 \text{ -- } d_3)$		
	$d_3$ is the greater of $d_1$ and $d_2$ .		
<b>8.6.1.1220</b>	<b>DMIN</b>	“d-min”	DOUBLE
	$(d_1 d_2 \text{ -- } d_3)$		
	$d_3$ is the lesser of $d_1$ and $d_2$ .		
<b>8.6.1.1230</b>	<b>DNEGATE</b>	“d-negate”	DOUBLE
	$(d_1 \text{ -- } d_2)$		
	$d_2$ is the negation of $d_1$ .		
<b>8.6.1.1820</b>	<b>M*/</b>	“m-star-slash”	DOUBLE
	$(d_1 n_1 + n_2 \text{ -- } d_2)$		
	Multiply $d_1$ by $n_1$ producing the triple-cell intermediate result $t$ . Divide $t$ by $+n_2$ giving the double-cell quotient $d_2$ . An ambiguous condition exists if $+n_2$ is zero or negative, or the quotient lies outside of the range of a double-precision signed integer.		
	See: <a href="#">A.8.6.1.1820 M*/</a> .		
<b>8.6.1.1830</b>	<b>M+</b>	“m-plus”	DOUBLE
	$(d_1 \mid ud_1 n \text{ -- } d_2 \mid ud_2)$		
	Add $n$ to $d_1 \mid ud_1$ , giving the sum $d_2 \mid ud_2$ .		
	See: <a href="#">A.8.6.1.1830 M+</a> .		

## 9 The optional Exception word set

### 9.1 Introduction

### 9.2 Additional terms and notation

None.

### 9.3 Additional usage requirements

#### 9.3.1 THROW values

The **THROW** values  $\{-255 \dots -1\}$  shall be used only as assigned by this standard. The values  $\{-4095 \dots -256\}$  shall be used only as assigned by a system.

Programs shall not define values for use with **THROW** in the range  $\{-4095 \dots -1\}$ .

#### 9.3.2 Exception frame

An exception frame is the implementation-dependent set of information recording the current execution state necessary for the proper functioning of **CATCH** and **THROW**. It often includes the depths of the data stack and return stack.

#### 9.3.3 Exception stack

A stack used for the nesting of exception frames by **CATCH** and **THROW**. It may be, but need not be, implemented using the return stack.

#### 9.3.4 Possible actions on an ambiguous condition

A system choosing to execute **THROW** when detecting one of the ambiguous conditions listed in table 9.1 shall use the throw code listed there.

See: [3.4.4 Possible actions on an ambiguous condition](#).

#### 9.3.5 Exception handling

There are several methods of coupling **CATCH** and **THROW** to other procedural nestings. The usual nestings are the execution of definitions, use of the return stack, use of loops, instantiation of locals and nesting of input sources (i.e., with **LOAD**, **EVALUATE**, or **INCLUDE-FILE**).

When a **THROW** returns control to a **CATCH**, the system shall un-nest not only definitions, but also, if present, locals and input source specifications, to return the system to its proper state for continued execution past the **CATCH**.

Table 9.1: **THROW** code assignments

Code Reserved for	Code Reserved for
-1 <b>ABORT</b>	-40 invalid <b>BASE</b> for floating point conversion
-2 <b>ABORT"</b>	-41 loss of precision
-3 stack overflow	-42 floating-point divide by zero
-4 stack underflow	-43 floating-point result out of range
-5 return stack overflow	-44 floating-point stack overflow
-6 return stack underflow	-45 floating-point stack underflow
-7 do-loops nested too deeply during execution	-46 floating-point invalid argument
-8 dictionary overflow	-47 compilation word list deleted
-9 invalid memory address	-48 invalid <b>POSTPONE</b>
-10 division by zero	-49 search-order overflow
-11 result out of range	-50 search-order underflow
-12 argument type mismatch	-51 compilation word list changed
-13 undefined word	-52 control-flow stack overflow
-14 interpreting a compile-only word	-53 exception stack overflow
-15 invalid <b>FORGET</b>	-54 floating-point underflow
-16 attempt to use zero-length string as a name	-55 floating-point unidentified fault
-17 pictured numeric output string overflow	-56 <b>QUIT</b>
-18 parsed string overflow	-57 exception in sending or receiving a character
-19 definition name too long	-58 <b>[IF]</b> , <b>[ELSE]</b> , or <b>[THEN]</b> exception
-20 write to a read-only location	-59 <b>ALLOCATE</b>
-21 unsupported operation (e.g., <b>AT-XY</b> on a too-dumb terminal)	-60 <b>FREE</b>
-22 control structure mismatch	-61 <b>RESIZE</b>
-23 address alignment exception	-62 <b>CLOSE-FILE</b>
-24 invalid numeric argument	-63 <b>CREATE-FILE</b>
-25 return stack imbalance	-64 <b>DELETE-FILE</b>
-26 loop parameters unavailable	-65 <b>FILE-POSITION</b>
-27 invalid recursion	-66 <b>FILE-SIZE</b>
-28 user interrupt	-67 <b>FILE-STATUS</b>
-29 compiler nesting	-68 <b>FLUSH-FILE</b>
-30 obsolescent feature	-69 <b>OPEN-FILE</b>
-31 <b>&gt;BODY</b> used on non- <b>CREATE</b> d definition	-70 <b>READ-FILE</b>
-32 invalid <i>name</i> argument (e.g., <b>TO name</b> )	-71 <b>READ-LINE</b>
-33 block read exception	-72 <b>RENAME-FILE</b>
-34 block write exception	-73 <b>REPOSITION-FILE</b>
-35 invalid block number	-74 <b>RESIZE-FILE</b>
-36 invalid file position	-75 <b>WRITE-FILE</b>
-37 file I/O exception	-76 <b>WRITE-LINE</b>
-38 non-existent file	-77 Malformed xchar
-39 unexpected end of file	-78 <b>SUBSTITUTE</b>
	-79 <b>REPLACES</b>

## 9.4 Additional documentation requirements

### 9.4.1 System documentation

#### 9.4.1.1 Implementation-defined options

- Values used in the system by [9.6.1.0875 CATCH](#) and [9.6.1.2275 THROW](#) ([9.3.1 THROW values](#), [9.3.4 Possible actions on an ambiguous condition](#)).

#### 9.4.1.2 Ambiguous conditions

- no additional requirements.

#### 9.4.1.3 Other system documentation

- no additional requirements.

### 9.4.2 Program documentation

- no additional requirements.

## 9.5 Compliance and labeling

### 9.5.1 Forth-2012 systems

The phrase “Providing the Exception word set” shall be appended to the label of any Standard System that provides all of the Exception word set.

The phrase “Providing *name(s)* from the Exception Extensions word set” shall be appended to the label of any Standard System that provides portions of the Exception Extensions word set.

The phrase “Providing the Exception Extensions word set” shall be appended to the label of any Standard System that provides all of the Exception and Exception Extensions word sets.

### 9.5.2 Forth-2012 programs

The phrase “Requiring the Exception word set” shall be appended to the label of Standard Programs that require the system to provide the Exception word set.

The phrase “Requiring *name(s)* from the Exception Extensions word set” shall be appended to the label of Standard Programs that require the system to provide portions of the Exception Extensions word set.

The phrase “Requiring the Exception Extensions word set” shall be appended to the label of Standard Programs that require the system to provide all of the Exception and Exception Extensions word sets.

## 9.6 Glossary

### 9.6.1 Exception words

9.6.1.0875    **CATCH**    EXCEPTION

$(i^*x\ xt\ --\ j^*x\ 0\ | \ i^*x\ n)$

Push an exception frame on the exception stack and then execute the execution token *xt* (as with **EXECUTE**) in such a way that control can be transferred to a point just after **CATCH** if **THROW** is executed during the execution of *xt*.

If the execution of *xt* completes normally (i.e., the exception frame pushed by this **CATCH** is not popped by an execution of **THROW**) pop the exception frame and return zero on top of the data stack, above whatever stack items would have been returned by *xt* **EXECUTE**. Otherwise, the remainder of the execution semantics are given by **THROW**.

See: [A.9.6.1.2275](#) **THROW**.

9.6.1.2275    **THROW**    EXCEPTION

$(k^*x\ n\ --\ k^*x\ | \ i^*x\ n)$

If any bits of *n* are non-zero, pop the topmost exception frame from the exception stack, along with everything on the return stack above that frame. Then restore the input source specification in use before the corresponding **CATCH** and adjust the depths of all stacks defined by this standard so that they are the same as the depths saved in the exception frame (*i* is the same number as the *i* in the input arguments to the corresponding **CATCH**), put *n* on top of the data stack, and transfer control to a point just after the **CATCH** that pushed that exception frame.

If the top of the stack is non zero and there is no exception frame on the exception stack, the behavior is as follows:

If *n* is minus-one (-1), perform the function of [6.1.0670](#) **ABORT** (the version of **ABORT** in the Core word set), displaying no message.

If *n* is minus-two, perform the function of [6.1.0680](#) **ABORT"** (the version of **ABORT"** in the Core word set), displaying the characters *ccc* associated with the **ABORT"** that generated the **THROW**.

Otherwise, the system may display an implementation-dependent message giving information about the condition associated with the **THROW** code *n*. Subsequently, the system shall perform the function of [6.1.0670](#) **ABORT** (the version of **ABORT** in the Core word set).

See: [A.9.6.1.2275](#) **THROW**.

## 9.6.2 Exception extension words

**9.6.2.0670 ABORT** EXCEPTION EXT

Extend the semantics of [6.1.0670 ABORT](#) to be:

$(i * x \text{ -- } ) (R: j * x \text{ -- } )$

Perform the function of -1 [THROW](#).

See: [6.1.0670 ABORT](#).

**9.6.2.0680 ABORT"** "abort-quote" EXCEPTION EXT

Extend the semantics of [6.1.0680 ABORT"](#) to be:

Interpretation: Interpretation semantics for this word are undefined.

Compilation:  $( \text{“}ccc\langle quote \rangle \text{”} \text{ -- } )$

Parse *ccc* delimited by a " (double-quote). Append the run-time semantics given below to the current definition.

Run-time:  $(i * x \ x_j \text{ -- } | i * x) (R: j * x \text{ -- } | j * x)$

Remove  $x_j$  from the stack. If any bit of  $x_j$  is not zero, perform the function of -2 [THROW](#), displaying *ccc* if there is no exception frame on the exception stack.

See: [3.4.1 Parsing](#), [6.1.0680 ABORT"](#).

## 10 The optional Facility word set

### 10.1 Introduction

### 10.2 Additional terms and notation

None.

### 10.3 Additional usage requirements

#### 10.3.1 Data types

Append table 10.1 to table 3.1.

Table 10.1: Data types

<i>Symbol</i>	<i>Data type</i>	<i>Size on stack</i>
<i>struct-sys</i>	data structures	implementation dependent

##### 10.3.1.1 Structure type

The implementation-dependent data generated upon beginning to compile a **BEGIN-STRUCTURE** ... **END-STRUCTURE** structure and consumed at its close is represented by the symbol *struct-sys* throughout this standard.

##### 10.3.1.2 Character types

Programs that use more than seven bits of a character by **EKEY** have an environmental dependency.

See: [3.1.2 Character types](#).

## 10.4 Additional documentation requirements

### 10.4.1 System documentation

#### 10.4.1.1 Implementation-defined options

- encoding of keyboard events [10.6.2.1305 EKEY](#));
- duration of a system clock tick;
- repeatability to be expected from execution of [10.6.2.1905 MS](#).

#### 10.4.1.2 Ambiguous conditions

- [10.6.1.0742 AT-XY](#) operation can't be performed on user output device;
- A *name* defined by [10.6.2.0763 BEGIN-STRUCTURE](#) is executed before the corresponding [10.6.2.1336 END-STRUCTURE](#) has been executed.

**10.4.1.3 Other system documentation**

- no additional requirements.

**10.4.2 Program documentation****10.4.2.1 Environmental dependencies**

- using more than seven bits of a character in [10.6.2.1305 EKEY](#).

**10.4.2.2 Other program documentation**

- no additional requirements.

**10.5 Compliance and labeling****10.5.1 Forth-2012 systems**

The phrase “Providing the Facility word set” shall be appended to the label of any Standard System that provides all of the Facility word set.

The phrase “Providing *name(s)* from the Facility Extensions word set” shall be appended to the label of any Standard System that provides portions of the Facility Extensions word set.

The phrase “Providing the Facility Extensions word set” shall be appended to the label of any Standard System that provides all of the Facility and Facility Extensions word sets.

**10.5.2 Forth-2012 programs**

The phrase “Requiring the Facility word set” shall be appended to the label of Standard Programs that require the system to provide the Facility word set.

The phrase “Requiring *name(s)* from the Facility Extensions word set” shall be appended to the label of Standard Programs that require the system to provide portions of the Facility Extensions word set.

The phrase “Requiring the Facility Extensions word set” shall be appended to the label of Standard Programs that require the system to provide all of the Facility and Facility Extensions word sets.

**10.6 Glossary****10.6.1 Facility words**

**10.6.1.0742 AT-XY** “at-x-y” FACILITY

(  $u_1$   $u_2$  -- )

Perform implementation-dependent steps so that the next character displayed will appear in column  $u_1$ , row  $u_2$  of the user output device, the upper left corner of which is column zero, row zero. An ambiguous condition exists if the operation cannot be performed on the user output device with the specified parameters.

**10.6.1.1755**    **KEY?**    “key-question”    FACILITY

( -- *flag* )

If a character is available, return *true*. Otherwise, return *false*. If non-character keyboard events are available before the first valid character, they are discarded and are subsequently unavailable. The character shall be returned by the next execution of **KEY**.

After **KEY?** returns with a value of *true*, subsequent executions of **KEY?** prior to the execution of **KEY** or **EKEY** also return *true*, without discarding keyboard events.

See: [A.10.6.1.1755 KEY?](#).

**10.6.1.2005**    **PAGE**    FACILITY

( -- )

Move to another page for output. Actual function depends on the output device. On a terminal, **PAGE** clears the screen and resets the cursor position to the upper left corner. On a printer, **PAGE** performs a form feed.

## 10.6.2 Facility extension words

**10.6.2.0135**    **+FIELD**    “plus-field”    FACILITY EXT  
X:structures

(  $n_1$   $n_2$  “*{spaces}name*” --  $n_3$  )

Skip leading space delimiters. Parse *name* delimited by a space. Create a definition for *name* with the execution semantics defined below. Return  $n_3 = n_1 + n_2$  where  $n_1$  is the offset in the data structure before **+FIELD** executes, and  $n_2$  is the size of the data to be added to the data structure.  $n_1$  and  $n_2$  are in address units.

*name* Execution: (  $addr_1$  --  $addr_2$  )

Add  $n_1$  to  $addr_1$  giving  $addr_2$ .

See: [10.6.2.0763 BEGIN-STRUCTURE](#), [10.6.2.1336 END-STRUCTURE](#),  
[10.6.2.0893 CFIELD:](#), [10.6.2.1518 FIELD:](#), [12.6.2.1517 FFIELD:](#),  
[12.6.2.2206.40 SFFIELD:](#), [12.6.2.1207.40 DFFIELD:](#), [A.10.6.2.0135 +FIELD](#).

**10.6.2.0763**    **BEGIN-STRUCTURE**    FACILITY EXT  
X:structures

( “*{spaces}name*” -- *struct-sys* 0 )

Skip leading space delimiters. Parse *name* delimited by a space. Create a definition for *name* with the execution semantics defined below. Return a *struct-sys* (zero or more implementation dependent items) that will be used by **END-STRUCTURE** and an initial offset of 0.

*name* Execution: ( -- +*n* )

+*n* is the size in memory expressed in address units of the data structure. An ambiguous condition exists if *name* is executed prior to the associated **END-STRUCTURE** being executed.

See: [10.6.2.0135](#) **+FIELD**, [10.6.2.1336](#) **END-STRUCTURE**,  
[A.10.6.2.0763](#) **BEGIN-STRUCTURE**.

x:reset

**10.6.2.0893 CFIELD :** “c-field-colon” FACILITY EXT  
X:structures

( *n*<sub>1</sub> “*spaces*”*name* -- *n*<sub>2</sub> )

Skip leading space delimiters. Parse *name* delimited by a space. *Offset* is the first character aligned value greater than or equal to *n*<sub>1</sub>. *n*<sub>2</sub> = *offset* + 1 character.

Create a definition for *name* with the execution semantics given below.

*name* Execution: ( *addr*<sub>1</sub> -- *addr*<sub>2</sub> )

Add the *offset* calculated during the compile-time action to *addr*<sub>1</sub> giving the address *addr*<sub>2</sub>.

See: [10.6.2.0135](#) **+FIELD**, [10.6.2.0763](#) **BEGIN-STRUCTURE**,  
[10.6.2.1336](#) **END-STRUCTURE**, [A.10.6.2.1518](#) **FIELD :**.

**10.6.2.1305 EKEY** “e-key” FACILITY EXT

( -- *x* )

Receive one keyboard event *x*. The encoding of keyboard events is implementation defined.

See: [6.1.1750](#) **KEY**, [10.6.1.1755](#) **KEY?**, [A.10.6.2.1305](#) **EKEY**.

**10.6.2.1306 EKEY>CHAR** “e-key-to-char” FACILITY EXT

( *x* -- *x false* | *char true* )

If the keyboard event *x* corresponds to a character in the implementation-defined character set, return that character and *true*. Otherwise return *x* and *false*.

See: [A.10.6.2.1306](#) **EKEY>CHAR**.

x:reset

**10.6.2.1306.40 EKEY>FKEY** “e-key-to-f-key” FACILITY EXT  
X:ekeys

( *x* -- *u flag* )

If the keyboard event *x* corresponds to a keypress in the implementation-defined special key set, return that key’s id *u* and *true*. Otherwise return *x* and *false*.

Note: The keyboard may lack some of the keys, or the capability to report them. Programs should be written such that they also work (although less conveniently or with less functionality) if these key numbers cannot be produced.

See: [10.6.2.1305](#) EKEY, [10.6.2.1740.01](#) K-ALT-MASK, [10.6.2.1740.02](#) K-CTRL-MASK, [10.6.2.1740.03](#) K-DELETE, [10.6.2.1740.04](#) K-DOWN, [10.6.2.1740.05](#) K-END, [10.6.2.1740.06](#) K-F1, [10.6.2.1740.07](#) K-F10, [10.6.2.1740.08](#) K-F11, [10.6.2.1740.09](#) K-F12, [10.6.2.1740.10](#) K-F2, [10.6.2.1740.11](#) K-F3, [10.6.2.1740.12](#) K-F4, [10.6.2.1740.13](#) K-F5, [10.6.2.1740.14](#) K-F6, [10.6.2.1740.15](#) K-F7, [10.6.2.1740.16](#) K-F8, [10.6.2.1740.17](#) K-F9, [10.6.2.1740.18](#) K-HOME, [10.6.2.1740.19](#) K-INSERT, [10.6.2.1740.20](#) K-LEFT, [10.6.2.1740.21](#) K-NEXT, [10.6.2.1740.22](#) K-PRIOR, [10.6.2.1740.23](#) K-RIGHT, [10.6.2.1740.24](#) K-SHIFT-MASK, [10.6.2.1740.25](#) K-UP, [A.10.6.2.1306.40](#) EKEY>FKEY.

**10.6.2.1307**    **EKEY?**    “e-key-question”    FACILITY EXT

( -- *flag* )

If a keyboard event is available, return *true*. Otherwise return *false*. The event shall be returned by the next execution of **EKEY**.

After **EKEY?** returns with a value of *true*, subsequent executions of **EKEY?** prior to the execution of **KEY**, **KEY?** or **EKEY** also return *true*, referring to the same event.

**10.6.2.1325**    **EMIT?**    “emit-question”    FACILITY EXT

( -- *flag* )

*flag* is true if the user output device is ready to accept data and the execution of **EMIT** in place of **EMIT?** would not have suffered an indefinite delay. If the device status is indeterminate, *flag* is true.

See: [A.10.6.2.1325](#) EMIT?.

x:reset

**10.6.2.1336**    **END-STRUCTURE**    FACILITY EXT  
X:structures

( *struct-sys* +*n* -- )

Terminate definition of a structure started by **BEGIN-STRUCTURE**.

See: [10.6.2.0135](#) +FIELD, [10.6.2.0763](#) BEGIN-STRUCTURE.

**10.6.2.1518 FIELD:** “field-colon” FACILITY EXT  
X:structures

(  $n_1$  “*spaces*” *name* --  $n_2$  )

Skip leading space delimiters. Parse *name* delimited by a space. *Offset* is the first cell aligned value greater than or equal to  $n_1$ .  $n_2 = offset + 1$  cell.

Create a definition for *name* with the execution semantics given below.

*name* Execution: (  $addr_1$  --  $addr_2$  )

Add the *offset* calculated during the compile-time action to  $addr_1$  giving the address  $addr_2$ .

See: [10.6.2.0135](#) +FIELD, [10.6.2.0763](#) BEGIN-STRUCTURE,  
[10.6.2.1336](#) END-STRUCTURE, [A.10.6.2.1518](#) FIELD:.

**10.6.2.1740.01 K-ALT-MASK** FACILITY EXT  
X:keys

( -- *u* )

Mask for the ALT key, that can be **OR**ed with the key value to produce a value that the sequence **EKEY EKEY>FKEY** may produce when the user presses the corresponding key combination.

See: [10.6.2.1306.40](#) EKEY>FKEY, [A.10.6.2.1306.40](#) EKEY>FKEY.

**10.6.2.1740.02 K-CTRL-MASK** FACILITY EXT  
X:keys

( -- *u* )

Mask for the CTRL key, that can be **OR**ed with the key value to produce a value that the sequence **EKEY EKEY>FKEY** may produce when the user presses the corresponding key combination.

See: [10.6.2.1306.40](#) EKEY>FKEY, [A.10.6.2.1306.40](#) EKEY>FKEY.

**10.6.2.1740.03 K-DELETE** FACILITY EXT  
X:keys

( -- *u* )

Leaves the value *u* that the sequence **EKEY EKEY>FKEY** would produce when the user presses the “Delete” key.

See: [10.6.2.1306.40](#) EKEY>FKEY, [A.10.6.2.1306.40](#) EKEY>FKEY.

**10.6.2.1740.04 K-DOWN**FACILITY EXT  
X:ekeys( -- *u* )

Leaves the value *u* that the sequence **EKEY EKEY>FKEY** would produce when the user presses the “cursor down” key.

**10.6.2.1905 MS**

FACILITY EXT

( *u* -- )

Wait at least *u* milliseconds.

Note: The actual length and variability of the time period depends upon the implementation-defined resolution of the system clock and upon other system and computer characteristics beyond the scope of this standard.

See: [A.10.6.2.1905 MS](#).

**10.6.2.2292 TIME&DATE**

“time-and-date”

FACILITY EXT

( -- +*n*<sub>1</sub> +*n*<sub>2</sub> +*n*<sub>3</sub> +*n*<sub>4</sub> +*n*<sub>5</sub> +*n*<sub>6</sub> )

Return the current time and date. +*n*<sub>1</sub> is the second {0..59}, +*n*<sub>2</sub> is the minute {0..59}, +*n*<sub>3</sub> is the hour {0..23}, +*n*<sub>4</sub> is the day {1..31}, +*n*<sub>5</sub> is the month {1..12} and +*n*<sub>6</sub> is the year (e.g., 1991).

See: [A.10.6.2.2292 TIME&DATE](#).

## 11 The optional File-Access word set

### 11.1 Introduction

These words provide access to mass storage in the form of “files” under the following assumptions:

- files are provided by a host operating system;
- file names are represented as character strings;
- the format of file names is determined by the host operating system;
- an open file is identified by a single-cell file identifier (*fileid*);
- file-state information (e.g., position, size) is managed by the host operating system;
- file contents are accessed as a sequence of characters;
- file read operations return an actual transfer count, which can differ from the requested transfer count.

### 11.2 Additional terms

**file-access method:** A permissible means of accessing a file, such as “read/write” or “read only”.

**file position:** The character offset from the start of the file.

**input file:** The file, containing a sequence of lines, that is the input source.

### 11.3 Additional usage requirements

#### 11.3.1 Data types

Append table 11.1 to table 3.1.

Table 11.1: Data types

<i>Symbol</i>	<i>Data type</i>	<i>Size on stack</i>
<i>fam</i>	file access method	1 cell
<i>fileid</i>	file identifier	1 cell

#### 11.3.1.1 File identifiers

File identifiers are implementation-dependent single-cell values that are passed to file operators to designate specific files. Opening a file assigns a file identifier, which remains valid until closed.

#### 11.3.1.3 File access methods (11.3.1.3)

File access methods are implementation-defined single-cell values.

#### 11.3.1.4 File names

A character string containing the name of the file. The file name may include an implementation-dependent path name. The format of file names is implementation defined.

### 11.3.2 Blocks in files

Blocks may, but need not, reside in files. When they do:

- Block numbers may be mapped to one or more files by implementation-defined means. An ambiguous condition exists if a requested block number is not currently mapped;
- An **UPDATE**d block that came from a file shall be transferred back to the same file.

### 11.3.3 Input source

The File-Access word set creates another input source for the text interpreter. When the input source is a text file, **BLK** shall contain zero, **SOURCE-ID** shall contain the *fileid* of that text file, and the input buffer shall contain one line of the text file. During text interpretation from a text file, the value returned by **FILE-POSITION** for the *fileid* returned by **SOURCE-ID** is undefined. A standard program shall not call **REPOSITION-FILE** on the *fileid* returned by **SOURCE-ID**.

Input with **INCLUDED**, **INCLUDE-FILE**, **LOAD** and **EVALUATE** shall be nestable in any order to at least eight levels.

A program that uses more than eight levels of input-file nesting has an environmental dependency. See: [3.3.3.5 Input buffers](#), [9 The optional Exception word set](#).

### 11.3.4 Other transient regions

The system provides transient buffers for **S"** and **S\**" strings. These buffers shall be no less than 80 characters in length, and there shall be at least two buffers. The system should be able to store two strings defined by sequential use of **S"** or **S\**". RAM-limited systems may have environmental restrictions on the number of buffers and their lifetimes.

### 11.3.5 Parsing

When parsing from a text file using a space delimiter, control characters shall be treated the same as the space character.

Lines of at least 128 characters shall be supported. A program that requires lines of more than 128 characters has an environmental dependency.

A program may reposition the parse area within the input buffer by manipulating the contents of **>IN**. More extensive repositioning can be accomplished using **SAVE-INPUT** and **RESTORE-INPUT**.

See: [3.4.1 Parsing](#).

## 11.4 Additional documentation requirements

### 11.4.1 System documentation

#### 11.4.1.1 Implementation-defined options

- file access methods used by [11.6.1.0765 BIN](#), [11.6.1.1010 CREATE-FILE](#), [11.6.1.1970 OPEN-FILE](#), [11.6.1.2054 R/O](#), [11.6.1.2056 R/W](#) and [11.6.1.2425 W/O](#);
- file exceptions;

- file line terminator ([11.6.1.2090 READ-LINE](#));
- file name format ([11.3.1.4 File names](#));
- information returned by [11.6.2.1524 FILE-STATUS](#);
- input file state after an exception ([11.6.1.1717 INCLUDE-FILE](#), [11.6.1.1718 INCLUDED](#));
- maximum depth of file input nesting ([11.3.3 Input source](#));
- maximum size of input line ([11.3.5 Parsing](#));
- methods for mapping block ranges to files ([11.3.2 Blocks in files](#));
- number of string buffers provided ([11.3.4 Other transient regions](#));
- size of string buffer used by [11.3.4 Other transient regions](#).

#### 11.4.1.2 Ambiguous conditions

- attempting to position a file outside its boundaries ([11.6.1.2142 REPOSITION-FILE](#));
- attempting to read from file positions not yet written ([11.6.1.2080 READ-FILE](#), [11.6.1.2090 READ-LINE](#));
- *fileid* is invalid ([11.6.1.1717 INCLUDE-FILE](#));
- I/O exception reading or closing *fileid* ([11.6.1.1717 INCLUDE-FILE](#), [11.6.1.1718 INCLUDED](#));
- named file cannot be opened ([11.6.1.1718 INCLUDED](#));
- requesting an unmapped block number ([11.3.2 Blocks in files](#));
- using [11.6.1.2218 SOURCE-ID](#) when [7.6.1.0790 BLK](#) is not zero;
- a file is required while it is being [REQUIRED](#) ([11.6.2.2144.50](#)) or [INCLUDED](#) ([11.6.1.1718](#));
- a marker is defined outside and executed inside a file or vice versa, and the file is [REQUIRED](#) ([11.6.2.2144.50](#)) again;
- the same file is required twice using different names (e.g., through symbolic links), or different files with the same name are provided to [11.6.2.2144.50 REQUIRED](#) (by doing some renaming between the invocations of [REQUIRED](#));
- the stack effect of including with [11.6.2.2144.50 REQUIRED](#) the file is not ( $i*x -- i*x$ ).

#### 11.4.1.3 Other system documentation

- no additional requirements.

### 11.4.2 Program documentation

#### 11.4.2.1 Environmental dependencies

- requiring lines longer than 128 characters ([11.3.5 Parsing](#));
- using more than eight levels of input-file nesting ([11.3.3 Input source](#)).

**11.4.2.2 Other program documentation**

- no additional requirements.

**11.5 Compliance and labeling****11.5.1 Forth-2012 systems**

The phrase “Providing the File Access word set” shall be appended to the label of any Standard System that provides all of the File Access word set.

The phrase “Providing *name(s)* from the File Access Extensions word set” shall be appended to the label of any Standard System that provides portions of the File Access Extensions word set.

The phrase “Providing the File Access Extensions word set” shall be appended to the label of any Standard System that provides all of the File Access and File Access Extensions word sets.

**11.5.2 Forth-2012 programs**

The phrase “Requiring the File Access word set” shall be appended to the label of Standard Programs that require the system to provide the File Access word set.

The phrase “Requiring *name(s)* from the File Access Extensions word set” shall be appended to the label of Standard Programs that require the system to provide portions of the File Access Extensions word set.

The phrase “Requiring the File Access Extensions word set” shall be appended to the label of Standard Programs that require the system to provide all of the File Access and File Access Extensions word sets.

**11.6 Glossary****11.6.1 File Access words**

**11.6.1.0080** ( “paren” FILE

( “*ccc**<paren>*” -- )

Extend the semantics of [6.1.0080](#) ( to include:

When parsing from a text file, if the end of the parse area is reached before a right parenthesis is found, refill the input buffer from the next line of the file, set **>IN** to zero, and resume parsing, repeating this process until either a right parenthesis is found or the end of the file is reached.

**11.6.1.0765** **BIN** FILE

(*fam*<sub>1</sub> -- *fam*<sub>2</sub>)

Modify the implementation-defined file access method *fam*<sub>1</sub> to additionally select a “binary”, i.e., not line oriented, file access method, giving access method *fam*<sub>2</sub>.

See: [11.6.1.2054](#) R/O, [11.6.1.2056](#) R/W, [11.6.1.2425](#) W/O, [A.11.6.1.0765](#) BIN.

**11.6.1.0900 CLOSE-FILE** FILE

( *fileid* -- *ior* )

Close the file identified by *fileid*. *ior* is the implementation-defined I/O result code.

**11.6.1.1010 CREATE-FILE** FILE

( *c-addr u fam* -- *fileid ior* )

Create the file named in the character string specified by *c-addr* and *u*, and open it with file access method *fam*. The meaning of values of *fam* is implementation defined. If a file with the same name already exists, recreate it as an empty file.

If the file was successfully created and opened, *ior* is zero, *fileid* is its identifier, and the file has been positioned to the start of the file.

Otherwise, *ior* is the implementation-defined I/O result code and *fileid* is undefined.

See: [A.11.6.1.1010 CREATE-FILE](#).

**11.6.1.1190 DELETE-FILE** FILE

( *c-addr u* -- *ior* )

Delete the file named in the character string specified by *c-addr u*. *ior* is the implementation-defined I/O result code.

**11.6.1.1520 FILE-POSITION** FILE

( *fileid* -- *ud ior* )

*ud* is the current file position for the file identified by *fileid*. *ior* is the implementation-defined I/O result code. *ud* is undefined if *ior* is non-zero.

**11.6.1.1522 FILE-SIZE** FILE

( *fileid* -- *ud ior* )

*ud* is the size, in characters, of the file identified by *fileid*. *ior* is the implementation-defined I/O result code. This operation does not affect the value returned by [FILE-POSITION](#). *ud* is undefined if *ior* is non-zero.

**11.6.1.1717 INCLUDE-FILE**

FILE

 $(i * x \text{ fileid } -- j * x)$ 

Remove *fileid* from the stack. Save the current input source specification, including the current value of **SOURCE-ID**. Store *fileid* in **SOURCE-ID**. Make the file specified by *fileid* the input source. Store zero in **BLK**. Other stack effects are due to the words included.

Repeat until end of file: read a line from the file, fill the input buffer from the contents of that line, set **>IN** to zero, and interpret.

Text interpretation begins at the file position where the next file read would occur.

When the end of the file is reached, close the file and restore the input source specification to its saved value.

An ambiguous condition exists if *fileid* is invalid, if there is an I/O exception reading *fileid*, or if an I/O exception occurs while closing *fileid*. When an ambiguous condition exists, the status (open or closed) of any files that were being interpreted is implementation-defined.

See: [11.3.3 Input source](#), [A.11.6.1.1717 INCLUDE-FILE](#).

**11.6.1.1718 INCLUDED**

FILE

 $(i * x \text{ c-addr } u -- j * x)$ 

Remove *c-addr u* from the stack. Save the current input source specification, including the current value of **SOURCE-ID**. Open the file specified by *c-addr u*, store the resulting *fileid* in **SOURCE-ID**, and make it the input source. Store zero in **BLK**. Other stack effects are due to the words included.

Repeat until end of file: read a line from the file, fill the input buffer from the contents of that line, set **>IN** to zero, and interpret.

Text interpretation begins at the start of the file.

When the end of the file is reached, close the file and restore the input source specification to its saved value.

An ambiguous condition exists if the named file can not be opened, if an I/O exception occurs reading the file, or if an I/O exception occurs while closing the file. When an ambiguous condition exists, the status (open or closed) of any files that were being interpreted is implementation-defined.

**INCLUDED** may allocate memory in data space before it starts interpreting the file.

See: [11.6.1.1717 INCLUDE-FILE](#), [A.11.6.1.1718 INCLUDED](#).

**11.6.1.1970 OPEN-FILE** FILE

( *c-addr u fam -- fileid ior* )

Open the file named in the character string specified by *c-addr u*, with file access method indicated by *fam*. The meaning of values of *fam* is implementation defined.

If the file is successfully opened, *ior* is zero, *fileid* is its identifier, and the file has been positioned to the start of the file.

Otherwise, *ior* is the implementation-defined I/O result code and *fileid* is undefined.

See: [A.11.6.1.1970 OPEN-FILE](#).

**11.6.1.2054 R/O** “r-o” FILE

( -- *fam* )

*fam* is the implementation-defined value for selecting the “read only” file access method.

See: [11.6.1.1010 CREATE-FILE](#), [11.6.1.1970 OPEN-FILE](#).

**11.6.1.2056 R/W** “r-w” FILE

( -- *fam* )

*fam* is the implementation-defined value for selecting the “read/write” file access method.

See: [11.6.1.1010 CREATE-FILE](#), [11.6.1.1970 OPEN-FILE](#).

**11.6.1.2080 READ-FILE** FILE

( *c-addr u<sub>1</sub> fileid -- u<sub>2</sub> ior* )

Read *u<sub>1</sub>* consecutive characters to *c-addr* from the current position of the file identified by *fileid*.

If *u<sub>1</sub>* characters are read without an exception, *ior* is zero and *u<sub>2</sub>* is equal to *u<sub>1</sub>*.

If the end of the file is reached before *u<sub>1</sub>* characters are read, *ior* is zero and *u<sub>2</sub>* is the number of characters actually read.

If the operation is initiated when the value returned by **FILE-POSITION** is equal to the value returned by **FILE-SIZE** for the file identified by *fileid*, *ior* is zero and *u<sub>2</sub>* is zero.

If an exception occurs, *ior* is the implementation-defined I/O result code, and *u<sub>2</sub>* is the number of characters transferred to *c-addr* without an exception.

An ambiguous condition exists if the operation is initiated when the value returned by **FILE-POSITION** is greater than the value returned by **FILE-SIZE** for the file identified by *fileid*, or if the requested operation attempts to read portions of the file not written.

At the conclusion of the operation, **FILE-POSITION** returns the next file position after the last character read.

See: [A.11.6.1.2080 READ-FILE](#).

#### 11.6.1.2090 READ-LINE

FILE

( *c-addr u<sub>1</sub> fileid -- u<sub>2</sub> flag ior* )

Read the next line from the file specified by *fileid* into memory at the address *c-addr*. At most *u<sub>1</sub>* characters are read. Up to two implementation-defined line-terminating characters may be read into memory at the end of the line, but are not included in the count *u<sub>2</sub>*. The line buffer provided by *c-addr* should be at least *u<sub>1</sub>+2* characters long.

If the operation succeeded, *flag* is true and *ior* is zero. If a line terminator was received before *u<sub>1</sub>* characters were read, then *u<sub>2</sub>* is the number of characters, not including the line terminator, actually read ( $0 \leq u_2 \leq u_1$ ). When  $u_1 = u_2$  the line terminator has yet to be reached.

If the operation is initiated when the value returned by **FILE-POSITION** is equal to the value returned by **FILE-SIZE** for the file identified by *fileid*, *flag* is false, *ior* is zero, and *u<sub>2</sub>* is zero. If *ior* is non-zero, an exception occurred during the operation and *ior* is the implementation-defined I/O result code.

An ambiguous condition exists if the operation is initiated when the value returned by **FILE-POSITION** is greater than the value returned by **FILE-SIZE** for the file identified by *fileid*, or if the requested operation attempts to read portions of the file not written.

At the conclusion of the operation, **FILE-POSITION** returns the next file position after the last character read.

See: [A.11.6.1.2090 READ-LINE](#).

#### 11.6.1.2142 REPOSITION-FILE

FILE

( *ud fileid -- ior* )

Reposition the file identified by *fileid* to *ud*. *ior* is the implementation-defined I/O result code. An ambiguous condition exists if the file is positioned outside the file boundaries.

At the conclusion of the operation, **FILE-POSITION** returns the value *ud*.

#### 11.6.1.2147 RESIZE-FILE

FILE

( *ud fileid -- ior* )

Set the size of the file identified by *fileid* to *ud*. *ior* is the implementation-defined I/O result code.

If the resultant file is larger than the file before the operation, the portion of the file added as a result of the operation might not have been written.

At the conclusion of the operation, **FILE-SIZE** returns the value *ud* and **FILE-POSITION** returns an unspecified value.

See: [11.6.1.2080 READ-FILE](#), [11.6.1.2090 READ-LINE](#).

**11.6.1.2165 S"** "s-quote" FILE

Extend the semantics of [6.1.2165 S"](#) to be:

Interpretation: ( "*ccc**<quote>*" -- *c-addr u* )

Parse *ccc* delimited by " (double quote). Store the resulting string in a transient buffer *c-addr u*.

Compilation: ( "*ccc**<quote>*" -- )

Parse *ccc* delimited by " (double quote). Append the run-time semantics given below to the current definition.

Run-time: ( -- *c-addr u* )

Return *c-addr* and *u* that describe a string consisting of the characters *ccc*.

See: [3.4.1 Parsing](#), [6.2.0855 C"](#), [6.1.2165 S"](#), [11.3.4 Other transient regions](#), [11.6.2.2266 S\](#)", [A.11.3.4 Other transient regions](#), [A.11.6.1.2165 S"](#).

**11.6.1.2218 SOURCE-ID** "source-i-d" FILE

( -- *0* | *-1* | *fileid* )

Extend [6.2.2218 SOURCE-ID](#) to include text-file input as follows:

<b>SOURCE-ID</b>	Input source
<i>fileid</i>	Text file " <i>fileid</i> "
<i>-1</i>	String (via <a href="#">EVALUATE</a> )
<i>0</i>	User input device

An ambiguous condition exists if **SOURCE-ID** is used when **BLK** contains a non-zero value.

**11.6.1.2425 W/O** "w-o" FILE

( -- *fam* )

*fam* is the implementation-defined value for selecting the "write only" file access method.

See: [11.6.1.1010 CREATE-FILE](#), [11.6.1.1970 OPEN-FILE](#).

**11.6.1.2480 WRITE-FILE** FILE

( *c-addr u fileid -- ior* )

Write *u* characters from *c-addr* to the file identified by *fileid* starting at its current position. *ior* is the implementation-defined I/O result code.

At the conclusion of the operation, **FILE-POSITION** returns the next file position after the last character written to the file, and **FILE-SIZE** returns a value greater than or equal to the value returned by **FILE-POSITION**.

See: [11.6.1.2080 READ-FILE](#), [11.6.1.2090 READ-LINE](#).

**11.6.1.2485 WRITE-LINE** FILE

( *c-addr u fileid -- ior* )

Write *u* characters from *c-addr* followed by the implementation-dependent line terminator to the file identified by *fileid* starting at its current position. *ior* is the implementation-defined I/O result code.

At the conclusion of the operation, **FILE-POSITION** returns the next file position after the last character written to the file, and **FILE-SIZE** returns a value greater than or equal to the value returned by **FILE-POSITION**.

See: [11.6.1.2080 READ-FILE](#), [11.6.1.2090 READ-LINE](#).

**11.6.2 File-Access extension words****11.6.2.1524 FILE-STATUS** FILE EXT

( *c-addr u -- x ior* )

Return the status of the file identified by the character string *c-addr u*. If the file exists, *ior* is zero; otherwise *ior* is the implementation-defined I/O result code. *x* contains implementation-defined information about the file.

**11.6.2.1560 FLUSH-FILE** FILE EXT

( *fileid -- ior* )

Attempt to force any buffered information written to the file referred to by *fileid* to be written to mass storage, and the size information for the file to be recorded in the storage directory if changed. If the operation is successful, *ior* is zero. Otherwise, it is an implementation-defined I/O result code.

x:reset

**11.6.2.1714 INCLUDE** FILE EXT  
X:required

$( i * x \text{ "name" } -- j * x )$

Skip leading white space and parse *name* delimited by a white space character. Push the address and length of the *name* on the stack and perform the function of **INCLUDED**.

See: [11.6.1.1718 INCLUDED](#), [A.11.6.2.1714 INCLUDE](#).

**11.6.2.2125 REFILL** FILE EXT

$( -- flag )$

Extend the execution semantics of [6.2.2125 REFILL](#) with the following:

When the input source is a text file, attempt to read the next line from the text-input file. If successful, make the result the current input buffer, set **>IN** to zero, and return *true*. Otherwise return *false*.

See: [6.2.2125 REFILL](#), [7.6.2.2125 REFILL](#).

**11.6.2.2130 RENAME-FILE** FILE EXT

$( c-addr_1 u_1 c-addr_2 u_2 -- ior )$

Rename the file named by the character string *c-addr<sub>1</sub> u<sub>1</sub>* to the name in the character string *c-addr<sub>2</sub> u<sub>2</sub>*. *ior* is the implementation-defined I/O result code.

**11.6.2.2144.10 REQUIRE** FILE EXT  
X:required

$( i * x \text{ "name" } -- i * x )$

Skip leading white space and parse *name* delimited by a white space character. Push the address and length of the *name* on the stack and perform the function of **REQUIRED**.

See: [11.6.2.2144.50 REQUIRED](#), [A.11.6.2.2144.10 REQUIRE](#).

**11.6.2.2144.50 REQUIRED** FILE EXT  
X:required

$( i * x c-addr u -- i * x )$

If the file specified by *c-addr u* has been **INCLUDED** or **REQUIRED** already, but not between the definition and execution of a marker (or equivalent usage of **FORGET**), discard *c-addr u*; otherwise, perform the function of **INCLUDED**.

An ambiguous condition exists if a file is **REQUIRED** while it is being **REQUIRED** or **INCLUDED**.

An ambiguous condition exists, if a marker is defined outside and executed inside a file or vice versa, and the file is **REQUIRED** again.

## 12 The optional Floating-Point word set

### 12.1 Introduction

### 12.2 Additional terms and notation

#### 12.2.1 Definition of terms

**float-aligned address:** The address of a memory location at which a floating-point number can be accessed.

**double-float-aligned address:** The address of a memory location at which a 64-bit IEEE double-precision floating-point number can be accessed.

**single-float-aligned address:** The address of a memory location at which a 32-bit IEEE single-precision floating-point number can be accessed.

**IEEE floating-point number:** A single- or double-precision floating-point number as defined in ANSI/IEEE 754-1985.

#### 12.2.2 Notation

##### 12.2.2.2 Stack notation

Floating-point stack notation is:

( F: *before* -- *after* )

A unified stack notation is provided for systems with the environmental restriction that the floating-point numbers are kept on the data stack.

### 12.3 Additional usage requirements

#### 12.3.1 Data types

Append table 12.1 to table 3.1.

Table 12.1: Data Types

<i>Symbol</i>	<i>Data type</i>	<i>Size on stack</i>
<i>df-addr</i>	double-float-aligned address	1 cell
<i>f-addr</i>	float-aligned address	1 cell
<i>r</i>	floating-point number	implementation-defined
<i>sf-addr</i>	single-float-aligned address	1 cell

##### 12.3.1.1 Addresses

The set of float-aligned addresses is an implementation-defined subset of the set of aligned addresses. Adding the size of a floating-point number to a float-aligned address shall produce a float-aligned address.

The set of double-float-aligned addresses is an implementation-defined subset of the set of aligned addresses. Adding the size of a 64-bit IEEE double-precision floating-point number to a double-float-aligned address shall produce a double-float-aligned address.

The set of single-float-aligned addresses is an implementation-defined subset of the set of aligned addresses. Adding the size of a 32-bit IEEE single-precision floating-point number to a single-float-aligned address shall produce a single-float-aligned address.

### 12.3.1.2 Floating-point numbers

The internal representation of a floating-point number, including the format and precision of the significand and the format and range of the exponent, is implementation defined.

Any rounding or truncation of floating-point numbers is implementation defined.

### 12.3.2 Floating-point operations

“Round to nearest” means round the result of a floating-point operation to the representable value nearest the result. If the two nearest representable values are equally near the result, the one having zero as its least significant bit shall be delivered.

“Round toward negative infinity” means round the result of a floating-point operation to the representable value nearest to and no greater than the result.

“Round toward zero” means round the result of a floating-point operation to the representable value nearest to zero, frequently referred to as “truncation”.

### 12.3.3 Floating-point stack

A last in, first out list that shall be used by all floating-point operators.

The width of the floating-point stack is implementation-defined. The floating-point stack shall be separate from the data and return stacks.

The size of a floating-point stack shall be at least 6 items.

A program that depends on the floating-point stack being larger than six items has an environmental dependency.

### 12.3.4 Environmental queries

Append table 12.2 to table 3.5.

See: [3.2.6 Environmental queries](#).

### 12.3.5 Address alignment

Since the address returned by a **CREATE**d word is not necessarily aligned for any particular class of floating-point data, a program shall align the address (to be float aligned, single-float aligned, or double-float aligned) before accessing floating-point data at the address.

See: [3.3.3.1 Address alignment](#), [12.3.1.1 Addresses](#).

Table 12.2: Environmental Query Strings

String	Value data type	Constant?	Meaning
FLOATING-STACK	<i>n</i>	yes	the maximum depth of the separate floating-point stack. On systems with the environmental restriction of keeping floating-point items on the data stack, $n = 0$ .
MAX-FLOAT	<i>r</i>	yes	largest usable floating-point number

### 12.3.6 Variables

A program may address memory in data space regions made available by **FVARIABLE**. These regions may be non-contiguous with regions subsequently allocated with **,** (comma) or **ALLOT**. See: [3.3.3.3 Variables](#).

### 12.3.7 Text interpreter input number conversion

If the Floating-Point word set is present in the dictionary and the current base is **DECIMAL**, the input number-conversion algorithm shall be extended to recognize floating-point numbers in this form:

$$\begin{aligned} \text{Convertible string} &:= \langle \text{significand} \rangle \langle \text{exponent} \rangle \\ \langle \text{significand} \rangle &:= [ \langle \text{sign} \rangle ] \langle \text{digits} \rangle [ \langle \text{digits0} \rangle ] \\ \langle \text{exponent} \rangle &:= \mathbf{E} [ \langle \text{sign} \rangle ] \langle \text{digits0} \rangle \\ \langle \text{sign} \rangle &:= \{ + | - \} \\ \langle \text{digits} \rangle &:= \langle \text{digit} \rangle \langle \text{digits0} \rangle \\ \langle \text{digits0} \rangle &:= \langle \text{digit} \rangle^* \\ \langle \text{digit} \rangle &:= \{ 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 \} \end{aligned}$$

These are examples of valid representations of floating-point numbers in program source:

```
1E      1.E      1.E0      +1.23E-1      -1.23E+1
```

See: [3.4.1.3 Text interpreter input number conversion](#), [12.6.1.0558 >FLOAT](#).

## 12.4 Additional documentation requirements

### 12.4.1 System documentation

#### 12.4.1.1 Implementation-defined options

- format and range of floating-point numbers ([12.3.1 Data types](#), [12.6.1.2143 REPRESENT](#));
- results of [12.6.1.2143 REPRESENT](#) when *float* is out of range;
- rounding or truncation of floating-point numbers ([12.3.1.2 Floating-point numbers](#));
- size of floating-point stack ([12.3.3 Floating-point stack](#));
- width of floating-point stack ([12.3.3 Floating-point stack](#)).

#### 12.4.1.2 Ambiguous conditions

- **DF@** or **DF!** is used with an address that is not double-float aligned;

- **F@** or **F!** is used with an address that is not float aligned;
- floating point result out of range (e.g., in [12.6.1.1430 F/](#));
- **SF@** or **SF!** is used with an address that is not single-float aligned;
- **BASE** is not decimal ([12.6.1.2143 REPRESENT](#), [12.6.2.1427 F.](#), [12.6.2.1513 FE.](#), [12.6.2.1613 FS.](#));
- both arguments equal zero ([12.6.2.1489 FATAN2](#));
- cosine of argument is zero for [12.6.2.1625 FTAN](#);
- *d* can't be precisely represented as *float* in [12.6.1.1130 D>F](#);
- dividing by zero ([12.6.1.1430 F/](#));
- exponent too big for conversion ([12.6.2.1203 DF!](#), [12.6.2.1204 DF@](#), [12.6.2.2202 SF!](#), [12.6.2.2203 SF@](#));
- *float* less than one ([12.6.2.1477 FACOSH](#));
- *float* less than or equal to minus-one ([12.6.2.1554 FLNPL](#));
- *float* less than or equal to zero ([12.6.2.1553 FLN](#), [12.6.2.1557 FLOG](#));
- *float* less than zero ([12.6.2.1618 FSQRT](#));
- *float* magnitude greater than one ([12.6.2.1476 FACOS](#), [12.6.2.1486 FASIN](#), [12.6.2.1491 FATANH](#));
- integer part of *float* can't be represented by *d* in [12.6.1.1470 F>D](#);
- string larger than pictured-numeric output area ([12.6.2.1427 F.](#), [12.6.2.1513 FE.](#), [12.6.2.1613 FS.](#));
- *n* can't be precisely represented as *float* in [12.6.2.2175 S>F](#);
- integer part of *float* can't be represented by *n* in [12.6.2.1471 F>S](#).

#### 12.4.1.3 Other system documentation

- no additional requirements.

#### 12.4.1.4 Environmental restrictions

- Keeping floating-point numbers on the data stack.

### 12.4.2 Program documentation

#### 12.4.2.1 Environmental dependencies

- requiring the floating-point stack to be larger than six items ([12.3.3 Floating-point stack](#));
- requiring floating-point numbers to be kept on the data stack, with *n* cells per floating point number.

#### 12.4.2.2 Other program documentation

- no additional requirements.

<b>12.6.1.1130</b>	<b>D&gt;F</b>	“d-to-f”	FLOATING
		$( d \text{ -- } ) ( F: \text{ -- } r )$ or $( d \text{ -- } r )$	
		<del><math>r</math> is the floating-point equivalent of <math>d</math>. An ambiguous condition exists if <math>d</math> cannot be precisely represented as a floating-point value.</del>	
		<u><math>r</math> is the floating-point value which is nearest to <math>d</math> in the sense of “round to nearest”.</u>	
		See: <a href="#">12.3.2 Floating-point operations.</a>	
<b>12.6.1.1400</b>	<b>F!</b>	“f-store”	FLOATING
		$( f \text{ -addr -- } ) ( F: r \text{ -- } )$ or $( r f \text{ -addr -- } )$	
		Store $r$ at $f\text{-addr}$ .	
<b>12.6.1.1410</b>	<b>F*</b>	“f-star”	FLOATING
		$( F: r_1 r_2 \text{ -- } r_3 )$ or $( r_1 r_2 \text{ -- } r_3 )$	
		Multiply $r_1$ by $r_2$ giving $r_3$ .	
<b>12.6.1.1420</b>	<b>F+</b>	“f-plus”	FLOATING
		$( F: r_1 r_2 \text{ -- } r_3 )$ or $( r_1 r_2 \text{ -- } r_3 )$	
		Add $r_1$ to $r_2$ giving the sum $r_3$ .	
<b>12.6.1.1425</b>	<b>F-</b>	“f-minus”	FLOATING
		$( F: r_1 r_2 \text{ -- } r_3 )$ or $( r_1 r_2 \text{ -- } r_3 )$	
		Subtract $r_2$ from $r_1$ , giving $r_3$ .	
<b>12.6.1.1430</b>	<b>F/</b>	“f-slash”	FLOATING
		$( F: r_1 r_2 \text{ -- } r_3 )$ or $( r_1 r_2 \text{ -- } r_3 )$	
		Divide $r_1$ by $r_2$ , giving the quotient $r_3$ . An ambiguous condition exists if $r_2$ is zero, or the quotient lies outside of the range of a floating-point number.	
<b>12.6.1.1440</b>	<b>F0&lt;</b>	“f-zero-less-than”	FLOATING
		$( \text{ -- } flag ) ( F: r \text{ -- } )$ or $( r \text{ -- } flag )$	
		$flag$ is true if and only if $r$ is less than zero.	

<b>12.6.1.1450</b>	<b>F0=</b>	“f-zero-equals”	FLOATING
		( <i>-- flag</i> ) ( F: <i>r --</i> ) or ( <i>r -- flag</i> )	
		<i>flag</i> is true if and only if <i>r</i> is equal to zero.	
<b>12.6.1.1460</b>	<b>F&lt;</b>	“f-less-than”	FLOATING
		( <i>-- flag</i> ) ( F: <i>r<sub>1</sub> r<sub>2</sub> --</i> ) or ( <i>r<sub>1</sub> r<sub>2</sub> -- flag</i> )	
		<i>flag</i> is true if and only if <i>r<sub>1</sub></i> is less than <i>r<sub>2</sub></i> .	
<b>12.6.1.1470</b>	<b>F&gt;D</b>	“f-to-d”	FLOATING
		( <i>-- d</i> ) ( F: <i>r --</i> ) or ( <i>r -- d</i> )	
		<i>d</i> is the double-cell signed-integer equivalent of the integer portion of <i>r</i> . The fractional portion of <i>r</i> is discarded. An ambiguous condition exists if the integer portion of <i>r</i> cannot be represented as a double-cell signed integer.	
		Note: Rounding the floating-point value prior to calling <b>F&gt;D</b> is advised, because <b>F&gt;D</b> rounds towards zero.	
<b>12.6.1.1472</b>	<b>F@</b>	“f-fetch”	FLOATING
		( <i>f-addr --</i> ) ( F: <i>-- r</i> ) or ( <i>f-addr -- r</i> )	
		<i>r</i> is the value stored at <i>f-addr</i> .	
<b>12.6.1.1479</b>	<b>FALIGN</b>	“f-align”	FLOATING
		( <i>--</i> )	
		If the data-space pointer is not float aligned, reserve enough data space to make it so.	
<b>12.6.1.1483</b>	<b>FALIGNED</b>	“f-aligned”	FLOATING
		( <i>addr -- f-addr</i> )	
		<i>f-addr</i> is the first float-aligned address greater than or equal to <i>addr</i> .	
<b>12.6.1.1492</b>	<b>FCONSTANT</b>	“f-constant”	FLOATING
		( “ <i>{spaces}name</i> ” <i>--</i> ) ( F: <i>r --</i> ) or ( <i>r</i> “ <i>{spaces}name</i> ” <i>--</i> )	
		Skip leading space delimiters. Parse <i>name</i> delimited by a space. Create a definition for <i>name</i> with the execution semantics defined below.	

<b>12.6.1.1556</b>	<b>FLOATS</b>		FLOATING
		$(n_1 \text{ -- } n_2)$	
		$n_2$ is the size in address units of $n_1$ floating-point numbers.	
<b>12.6.1.1558</b>	<b>FLOOR</b>		FLOATING
		$(F: r_1 \text{ -- } r_2)$ or $(r_1 \text{ -- } r_2)$	
		Round $r_1$ to an integral value using the “round toward negative infinity” rule, giving $r_2$ .	
		See: <a href="#">12.3.2 Floating-point operations</a> , <a href="#">12.6.1.1612 FROUND</a> , <a href="#">12.6.2.1627 FTRUNC</a> .	
<b>12.6.1.1562</b>	<b>FMAX</b>	“f-max”	FLOATING
		$(F: r_1 r_2 \text{ -- } r_3)$ or $(r_1 r_2 \text{ -- } r_3)$	
		$r_3$ is the greater of $r_1$ and $r_2$ .	
<b>12.6.1.1565</b>	<b>FMIN</b>	“f-min”	FLOATING
		$(F: r_1 r_2 \text{ -- } r_3)$ or $(r_1 r_2 \text{ -- } r_3)$	
		$r_3$ is the lesser of $r_1$ and $r_2$ .	
<b>12.6.1.1567</b>	<b>FNEGATE</b>	“f-negate”	FLOATING
		$(F: r_1 \text{ -- } r_2)$ or $(r_1 \text{ -- } r_2)$	
		$r_2$ is the negation of $r_1$ .	
<b>12.6.1.1600</b>	<b>FOVER</b>	“f-over”	FLOATING
		$(F: r_1 r_2 \text{ -- } r_1 r_2 r_1)$ or $(r_1 r_2 \text{ -- } r_1 r_2 r_1)$	
		Place a copy of $r_1$ on top of the floating-point stack.	
<b>12.6.1.1610</b>	<b>FROT</b>	“f-rote”	FLOATING
		$(F: r_1 r_2 r_3 \text{ -- } r_2 r_3 r_1)$ or $(r_1 r_2 r_3 \text{ -- } r_2 r_3 r_1)$	
		Rotate the top three floating-point stack entries.	

x:reset

**12.6.2.1207.40 DFFIELD :** “d-f-field-colon” FLOATING EXT  
X:structures

(  $n_1$  “*<spaces>name*” --  $n_2$  )

Skip leading space delimiters. Parse *name* delimited by a space. *Offset* is the first double-float aligned value greater than or equal to  $n_1$ .  $n_2 = offset + 1$  double-float.

Create a definition for *name* with the execution semantics given below.

*name* Execution: (  $addr_1$  --  $addr_2$  )

Add the *offset* calculated during the compile-time action to  $addr_1$  giving the address  $addr_2$ .

See: [10.6.2.0135 +FIELD](#), [10.6.2.0763 BEGIN-STRUCTURE](#),  
[10.6.2.1336 END-STRUCTURE](#), [A.10.6.2.1518 FIELD :.](#)

**12.6.2.1208 DFLOAT+** “d-float-plus” FLOATING EXT

(  $df-addr_1$  --  $df-addr_2$  )

Add the size in address units of a 64-bit IEEE double-precision number to  $df-addr_1$ , giving  $df-addr_2$ .

See: [12.3.1.1 Addresses](#).

**12.6.2.1209 DFLOATS** “d-floats” FLOATING EXT

(  $n_1$  --  $n_2$  )

$n_2$  is the size in address units of  $n_1$  64-bit IEEE double-precision numbers.

**12.6.2.1415 F\*\*** “f-star-star” FLOATING EXT

( F:  $r_1 r_2$  --  $r_3$  ) or (  $r_1 r_2$  --  $r_3$  )

Raise  $r_1$  to the power  $r_2$ , giving the product  $r_3$ .

**12.6.2.1427 F.** “f-dot” FLOATING EXT

( -- ) ( F:  $r$  -- ) or (  $r$  -- )

Display, with a trailing space, the top number on the floating-point stack using fixed-point notation:

[ - ] *<digits>*,*<digits0>*

An ambiguous condition exists if the value of **BASE** is not (decimal) ten or if the character string representation exceeds the size of the pictured numeric output string buffer.

See: [12.6.1.0558](#) >FLOAT, [A.12.6.2.1427](#) F.

x:reset

**12.6.2.1471 F>S** “F to S” FLOATING EXT  
X:stoftos

( -- n ) ( F: r -- ) or ( r -- n )

$n$  is the single-cell signed-integer equivalent of the integer portion of  $r$ . The fractional portion of  $r$  is discarded. An ambiguous condition exists if the integer portion of  $r$  cannot be represented as a single-cell signed integer.

Note: Rounding the floating-point value prior to calling **F>S** is advised, because **F>S** rounds towards zero.

See: [12.6.2.2175](#) S>F.

**12.6.2.1474 FABS** “f-abs” FLOATING EXT

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

$r_2$  is the absolute value of  $r_1$ .

**12.6.2.1476 FACOS** “f-a-cos” FLOATING EXT

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

$r_2$  is the principal radian angle whose cosine is  $r_1$ . An ambiguous condition exists if  $|r_1|$  is greater than one.

**12.6.2.1477 FACOSH** “f-a-cosh” FLOATING EXT

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

$r_2$  is the floating-point value whose hyperbolic cosine is  $r_1$ . An ambiguous condition exists if  $r_1$  is less than one.

**12.6.2.1484 FALOG** “f-a-log” FLOATING EXT

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

Raise ten to the power  $r_1$ , giving  $r_2$ .

<b>12.6.2.1486</b>	<b>FASIN</b>	“f-a-sine”	FLOATING EXT
	( F: $r_1$ -- $r_2$ ) or ( $r_1$ -- $r_2$ )		
	$r_2$ is the principal radian angle whose sine is $r_1$ . An ambiguous condition exists if $ r_1 $ is greater than one.		
<b>12.6.2.1487</b>	<b>FASINH</b>	“f-a-cinch”	FLOATING EXT
	( F: $r_1$ -- $r_2$ ) or ( $r_1$ -- $r_2$ )		
	$r_2$ is the floating-point value whose hyperbolic sine is $r_1$ .		
<b>12.6.2.1488</b>	<b>FATAN</b>	“f-a-tan”	FLOATING EXT
	( F: $r_1$ -- $r_2$ ) or ( $r_1$ -- $r_2$ )		
	$r_2$ is the principal radian angle whose tangent is $r_1$ .		
<b>12.6.2.1489</b>	<b>FATAN2</b>	“f-a-tan-two”	FLOATING EXT

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

$r_2$  is the natural logarithm of  $r_1$ . An ambiguous condition exists if  $r_1$  is less than or equal to zero.

**12.6.2.1554**    **FLNP1**    “f-l-n-p-one”    FLOATING EXT

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

$r_2$  is the natural logarithm of the quantity  $r_1$  plus one. An ambiguous condition exists if  $r_1$  is less than or equal to negative one.

See: [A.12.6.2.1554](#) [FLNP1](#).

**12.6.2.1557**    **FLOG**    “f-log”    FLOATING EXT

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

$r_2$  is the base-ten logarithm of  $r_1$ . An ambiguous condition exists if  $r_1$  is less than or equal to zero.

**12.6.2.1613**    **FS.**    “f-s-dot”    FLOATING EXT

( -- ) ( F:  $r$  -- ) or (  $r$  -- )

Display, with a trailing space, the top number on the floating-point stack in scientific notation:  $\langle \text{significand} \rangle \langle \text{exponent} \rangle$  where:

$$\begin{aligned} \langle \text{significand} \rangle &:= [-] \langle \text{digit} \rangle . \langle \text{digits0} \rangle \\ \langle \text{exponent} \rangle &:= \mathbf{E}[-] \langle \text{digits} \rangle \end{aligned}$$

An ambiguous condition exists if the value of **BASE** is not (decimal) ten or if the character string representation exceeds the size of the pictured numeric output string buffer.

See: [6.1.0750](#) [BASE](#), [12.3.2](#) [Floating-point operations](#), [12.6.1.2143](#) [REPRESENT](#).

**12.6.2.1614**    **FSIN**    “f-sine”    FLOATING EXT

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

$r_2$  is the sine of the radian angle  $r_1$ .

**12.6.2.1616**    **FSINCOS**    “f-sine-cos”    FLOATING EXT

( F:  $r_1$  --  $r_2$   $r_3$  ) or (  $r_1$  --  $r_2$   $r_3$  )

$r_2$  is the sine of the radian angle  $r_1$ .  $r_3$  is the cosine of the radian angle  $r_1$ .

See: [A.12.6.2.1489](#) [FATAN2](#).

**12.6.2.1617**    **FSINH**    “f-cinch”    FLOATING EXT

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

$r_2$  is the hyperbolic sine of  $r_1$ .

**12.6.2.1618 FSQRT** “f-square-root” FLOATING EXT

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

$r_2$  is the square root of  $r_1$ . An ambiguous condition exists if  $r_1$  is less than zero.

**12.6.2.1625 FTAN** “f-tan” FLOATING EXT

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

$r_2$  is the tangent of the radian angle  $r_1$ . An ambiguous condition exists if  $\cos(r_1)$  is zero.

**12.6.2.1626 FTANH** “f-tan-h” FLOATING EXT

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

$r_2$  is the hyperbolic tangent of  $r_1$ .

**12.6.2.1627 FTRUNC** “f-trunc” FLOATING EXT x:reset  
X:ftrunc

( F:  $r_1$  --  $r_2$  ) or (  $r_1$  --  $r_2$  )

Round  $r_1$  to an integral value using the “round towards zero” rule, giving  $r_2$ .

See: [12.3.2 Floating-point operations](#), [12.6.1.1612 FROUND](#), [12.6.1.1558 FLOOR](#).

**12.6.2.1628 FVALUE** “f-value” FLOATING EXT x:reset  
X:fvalue

( F:  $r$  -- ) ( “*{spaces}name*” -- ) or (  $r$  “*{spaces}name*” -- )

Skip leading space delimiters. Parse *name* delimited by a space. Create a definition for *name* with the execution semantics defined below, with an initial value equal to  $r$ .

*name* is referred to as a “f-value”.

*name* Execution: ( F: --  $r$  ) or ( --  $r$  )

Place  $r$  on the floating point stack. The value of  $r$  is that given when *name* was created, until the phrase “ $r$  **TO** *name*” is executed, causing a new value of  $r$  to be assigned to *name*.

**TO** *name* Run-time: ( F:  $r$  -- ) or (  $r$  -- )

Assign the value  $r$  to *name*.

See: [3.4.1 Parsing](#), [6.2.2295 TO](#)

**12.6.2.1640** **F~** “f-proximate” FLOATING EXT

( -- flag ) ( F:  $r_1 r_2 r_3$  -- ) or (  $r_1 r_2 r_3$  -- flag )

If  $r_3$  is positive, *flag* is true if the absolute value of ( $r_1$  minus  $r_2$ ) is less than  $r_3$ .

If  $r_3$  is zero, *flag* is true if the implementation-dependent encoding of  $r_1$  and  $r_2$  are exactly identical (positive and negative zero are unequal if they have distinct encodings).

If  $r_3$  is negative, *flag* is true if the absolute value of ( $r_1$  minus  $r_2$ ) is less than the absolute value of  $r_3$  times the sum of the absolute values of  $r_1$  and  $r_2$ .

See: [A.12.6.2.1640](#) F~.

**12.6.2.2035** **PRECISION** FLOATING EXT

( -- u )

Return the number of significant digits currently used by **F.**, **FE.**, or **FS.** as *u*.

x.reset

**12.6.2.2175** **S>F** “S to F” FLOATING EXT  
X:stoftos

( n -- ) ( F: -- r ) or ( n -- r )

~~*r* is the floating-point equivalent of the single-cell value *n*. An ambiguous condition exists if *n* can not be precisely represented as a floating-point value.~~

x.to-f-round

*r* is the floating-point value which is nearest to *n* in the sense of “round to nearest”.

See: [12.6.2.1471](#) F>S, [12.3.2 Floating-point operations](#).

**12.6.2.2200** **SET-PRECISION** FLOATING EXT

( u -- )

Set the number of significant digits currently used by **F.**, **FE.**, or **FS.** to *u*.

**12.6.2.2202** **SF!** “s-f-store” FLOATING EXT

( *sf-addr* -- ) ( F:  $r$  -- ) or (  $r$  *sf-addr* -- )

Store the floating-point number *r* as a 32-bit IEEE single-precision number at *sf-addr*. If the significand of the internal representation of *r* has more precision than the IEEE single-precision format, it will be rounded using the “round to nearest” rule. An ambiguous condition exists if the exponent of *r* is too large to be accommodated by the IEEE single-precision format.

See: [12.3.1.1 Addresses](#), [12.3.2 Floating-point operations](#).

**12.6.2.2203 SF@** “s-f-fetch” FLOATING EXT

( *sf-addr* -- ) ( F: -- *r* ) or ( *sf-addr* -- *r* )

Fetch the 32-bit IEEE single-precision number stored at *sf-addr* to the floating-point stack as *r* in the internal representation. If the IEEE single-precision significand has more precision than the internal representation, it will be rounded to the internal representation using the “round to nearest” rule. An ambiguous condition exists if the exponent of the IEEE single-precision representation is too large to be accommodated by the internal representation.

See: [12.3.1.1 Addresses](#), [12.3.2 Floating-point operations](#).

**12.6.2.2204 SFALIGN** “s-f-align” FLOATING EXT

( -- )

If the data-space pointer is not single-float aligned, reserve enough data space to make it so.

See: [12.3.1.1 Addresses](#).

**12.6.2.2206 SFALIGNED** “s-f-aligned” FLOATING EXT

( *addr* -- *sf-addr* )

*sf-addr* is the first single-float-aligned address greater than or equal to *addr*.

See: [12.3.1.1 Addresses](#).

**12.6.2.2206.40 SFFIELD:** “s-f-field-colon” FLOATING EXT  
X:structures

(  $n_1$  “*{spaces}name*” --  $n_2$  )

Skip leading space delimiters. Parse *name* delimited by a space. *Offset* is the first single-float aligned value greater than or equal to  $n_1$ .  $n_2 = offset + 1$  single-float.

Create a definition for *name* with the execution semantics given below.

*name* Execution: ( *addr*<sub>1</sub> -- *addr*<sub>2</sub> )

Add the *offset* calculated during the compile-time action to *addr*<sub>1</sub> giving the address *addr*<sub>2</sub>.

See: [10.6.2.0135 +FIELD](#), [10.6.2.0763 BEGIN-STRUCTURE](#),  
[10.6.2.1336 END-STRUCTURE](#), [A.10.6.2.1518 FIELD:.](#)

**12.6.2.2207 SFLOAT+** “s-float-plus” FLOATING EXT

$( sf-addr_1 -- sf-addr_2 )$

Add the size in address units of a 32-bit IEEE single-precision number to  $sf-addr_1$ , giving  $sf-addr_2$ .

See: [12.3.1.1 Addresses](#).

**12.6.2.2208 SFLOATS** “s-floats” FLOATING EXT

$( n_1 -- n_2 )$

$n_2$  is the size in address units of  $n_1$  32-bit IEEE single-precision numbers.

See: [12.3.1.1 Addresses](#).

## 13 The optional Locals word set

### 13.1 Introduction

### 13.2 Additional terms and notation

None.

### 13.3 Additional usage requirements

#### 13.3.1 Locals

A local is a data object whose execution semantics shall return its value, whose scope shall be limited to the definition in which it is declared, and whose use in a definition shall not preclude reentrancy or recursion.

#### 13.3.2 Environmental queries

Append table 13.1 to table 3.5.

See: [3.2.6 Environmental queries](#).

Table 13.1: Environmental Query Strings

String	Value data type	Constant?	Meaning
#LOCALS	<i>n</i>	yes	maximum number of local variables in a definition

#### 13.3.3 Processing locals

To support the locals word set, a system shall provide a mechanism to receive the messages defined by **(LOCAL)** and respond as described here.

During the compilation of a definition after **:** (colon), **:NONAME**, or **DOES>**, a program may begin sending local identifier messages to the system. The process shall begin when the first message is sent. The process shall end when the “last local” message is sent. The system shall keep track of the names, order, and number of identifiers contained in the complete sequence.

##### 13.3.3.1 Compilation semantics

The system, upon receipt of a sequence of local-identifier messages, shall take the following actions at compile time:

- a) Create temporary dictionary entries for each of the identifiers passed to **(LOCAL)**, such that each identifier will behave as a *local*. These temporary dictionary entries shall vanish at the end of the definition, denoted by **;** (semicolon), **;CODE**, or **DOES>**. The system need not maintain these identifiers in the same way it does other dictionary entries as long as they can be found by normal dictionary searching processes. Furthermore, if the Search-Order word set is present, local identifiers shall

always be searched before any of the word lists in any definable search order, and none of the Search-Order words shall change the locals' privileged position in the search order. Local identifiers may reside in mass storage.

- b) For each identifier passed to **(LOCAL)**, the system shall generate an appropriate code sequence that does the following at execution time:
- 1) Allocate a storage resource adequate to contain the value of a local. The storage shall be allocated in a way that does not preclude re-entrancy or recursion in the definition using the local.
  - 2) Initialize the value using the top item on the data stack. If more than one local is declared, the top item on the stack shall be moved into the first local identified, the next item shall be moved into the second, and so on.

The storage resource may be the return stack or may be implemented in other ways, such as in registers. The storage resource shall not be the data stack. Use of locals shall not restrict use of the data stack before or after the point of declaration.

- c) Arrange that any of the legitimate methods of terminating execution of a definition, specifically **;** (semicolon), **;** **CODE, DOES>** or **EXIT**, will release the storage resource allocated for the locals, if any, declared in that definition. **ABORT** shall release all local storage resources, and **CATCH / THROW** (if implemented) shall release such resources for all definitions whose execution is being terminated.
- d) Separate sets of locals may be declared in defining words before **DOES>** for use by the defining word, and after **DOES>** for use by the word defined.

A system implementing the Locals word set shall support the declaration of at least sixteen locals in a definition.

### 13.3.3.2 Syntax restrictions

Immediate words in a program may use **(LOCAL)** to implement syntaxes for local declarations with the following restrictions:

- a) A program shall not compile any executable code into the current definition between the time **(LOCAL)** is executed to identify the first local for that definition and the time of sending the single required "last local" message;
- b) The position in program source at which the sequence of **(LOCAL)** messages is sent, referred to here as the point at which locals are declared, shall not lie within the scope of any control structure;
- c) Locals shall not be declared until values previously placed on the return stack within the definition have been removed;
- d) After a definition's locals have been declared, a program may place data on the return stack. However, if this is done, locals shall not be accessed until those values have been removed from the return stack;
- e) Words that return execution tokens, such as **'** (tick), **[ ' ]**, or **FIND**, shall not be used with local names;

- f) A program that declares more than sixteen locals in a single definition has an environmental dependency;
- g) Locals may be accessed or updated within control structures, including do-loops;
- h) Local names shall not be referenced by **POSTPONE** and **[COMPILE]**.

See: [3.4 The Forth text interpreter](#).

## 13.4 Additional documentation requirements

### 13.4.1 System documentation

#### 13.4.1.1 Implementation-defined options

- maximum number of locals in a definition ([13.3.3 Processing locals](#), [13.6.2.1795 LOCALS |](#)).

#### 13.4.1.2 Ambiguous conditions

- executing a named *local* while in interpretation state ([13.6.1.0086 \(LOCAL\)](#));
- a local name ends in “:”, “[”, “^”;
- a local name is a single non-alphabetic character;
- the text between { : and : } extends over more than one line;
- { : ... : } is used more than once in a word.

#### 13.4.1.3 Other system documentation

- no additional requirements.

### 13.4.2 Program documentation

#### 13.4.2.1 Environmental dependencies

- declaring more than sixteen locals in a single definition ([13.3.3 Processing locals](#)).

#### 13.4.2.2 Other program documentation

- no additional requirements.

## 13.5 Compliance and labeling

### 13.5.1 Forth-2012 systems

The phrase “Providing the Locals word set” shall be appended to the label of any Standard System that provides all of the Locals word set.

The phrase “Providing *name(s)* from the Locals Extensions word set” shall be appended to the label of any Standard System that provides portions of the Locals Extensions word set.

The phrase “Providing the Locals Extensions word set” shall be appended to the label of any Standard System that provides all of the Locals and Locals Extensions word sets.

### 13.5.2 Forth-2012 programs

The phrase “Requiring the Locals word set” shall be appended to the label of Standard Programs that require the system to provide the Locals word set.

The phrase “Requiring *name(s)* from the Locals Extensions word set” shall be appended to the label of Standard Programs that require the system to provide portions of the Locals Extensions word set.

The phrase “Requiring the Locals Extensions word set” shall be appended to the label of Standard Programs that require the system to provide all of the Locals and Locals Extensions word sets.

## 13.6 Glossary

### 13.6.1 Locals words

**13.6.1.0086**    **(LOCAL)**    “paren-local-paren”    LOCAL

Interpretation: Interpretation semantics for this word are undefined.

Execution: ( *c-addr u* -- )

When executed during compilation, **(LOCAL)** passes a message to the system that has one of two meanings. If *u* is non-zero, the message identifies a new *local* whose definition name is given by the string of characters identified by *c-addr u*. If *u* is zero, the message is “last local” and *c-addr* has no significance.

The result of executing **(LOCAL)** during compilation of a definition is to create a set of named local identifiers, each of which is a definition name, that only have execution semantics within the scope of that definition’s source.

*local* Execution: ( -- *x* )

Push the local’s value, *x*, onto the stack. The local’s value is initialized as described in [13.3.3 Processing locals](#) and may be changed by preceding the local’s name with **TO**. An ambiguous condition exists when local is executed while in interpretation state.

**TO** *local* Run-time: ( *x* -- )

Assign the value *x* to the local value *local*.

Note: This word does not have special compilation semantics in the usual sense because it provides access to a system capability for use by other user-defined words that do have them. However, the locals facility as a whole and the sequence of messages passed defines specific usage rules with semantic implications that are described in detail in section [13.3.3 Processing locals](#).

Note: This word is not intended for direct use in a definition to declare that definition’s locals. It is instead used by system or user compiling words. These compiling words in turn define their own syntax, and may be used directly in definitions to declare locals. In this context, the syntax for **(LOCAL)** is defined in terms of a sequence of compile-time messages and is described in detail in section [13.3.3 Processing locals](#).

See: [3.4 The Forth text interpreter](#) and [6.2.2295 TO](#).

*name* Execution: ( -- *x* )

Place the value currently assigned to *name* on the stack. An ambiguous condition exists when *name* is executed while in interpretation state.

**TO** *name* Run-time: ( *x* -- )

Set *name* to the value *x*.

See: [2.2.5 BNF notation](#), [6.2.2405 VALUE](#), [6.2.2295 TO](#), [A.13.6.2.2550 { : .](#)

## 14 The optional Memory-Allocation word set

### 14.1 Introduction

### 14.2 Additional terms and notation

None.

### 14.3 Additional usage requirements

#### 14.3.3 Allocated regions (14.3.3)

A program may address memory in data space regions made available by **ALLOCATE** or **RESIZE** and not yet released by **FREE**.

See: [3.3.3 Data space](#).

### 14.4 Additional documentation requirements

None.

### 14.5 Compliance and labeling

#### 14.5.1 Forth-2012 systems

The phrase “Providing the Memory-Allocation word set” shall be appended to the label of any Standard System that provides all of the Memory-Allocation word set.

The phrase “Providing *name(s)* from the Memory-Allocation Extensions word set” shall be appended to the label of any Standard System that provides portions of the Memory-Allocation Extensions word set.

The phrase “Providing the Memory-Allocation Extensions word set” shall be appended to the label of any Standard System that provides all of the Memory-Allocation and Memory-Allocation Extensions word sets.

#### 14.5.2 Forth-2012 programs

The phrase “Requiring the Memory-Allocation word set” shall be appended to the label of Standard Programs that require the system to provide the Memory-Allocation word set.

The phrase “Requiring *name(s)* from the Memory-Allocation Extensions word set” shall be appended to the label of Standard Programs that require the system to provide portions of the Memory-Allocation Extensions word set.

The phrase “Requiring the Memory-Allocation Extensions word set” shall be appended to the label of Standard Programs that require the system to provide all of the Memory-Allocation and Memory-Allocation Extensions word sets.

## 14.6 Glossary

### 14.6.1 Memory-Allocation words

14.6.1.0707 **ALLOCATE** MEMORY

( *u* -- *a-addr ior* )

Allocate *u* address units of contiguous data space. The data-space pointer is unaffected by this operation. The initial content of the allocated space is undefined.

If the allocation succeeds, *a-addr* is the aligned starting address of the allocated space and *ior* is zero.

If the operation fails, *a-addr* does not represent a valid address and *ior* is the implementation-defined I/O result code.

See: [6.1.1650 HERE](#), [14.6.1.1605 FREE](#), [14.6.1.2145 RESIZE](#).

14.6.1.1605 **FREE** MEMORY

( *a-addr* -- *ior* )

Return the contiguous region of data space indicated by *a-addr* to the system for later allocation. *a-addr* shall indicate a region of data space that was previously obtained by [ALLOCATE](#) or [RESIZE](#). The data-space pointer is unaffected by this operation.

If the operation succeeds, *ior* is zero. If the operation fails, *ior* is the implementation-defined I/O result code.

See: [6.1.1650 HERE](#), [14.6.1.0707 ALLOCATE](#), [14.6.1.2145 RESIZE](#).

14.6.1.2145 **RESIZE** MEMORY

( *a-addr*<sub>1</sub> *u* -- *a-addr*<sub>2</sub> *ior* )

Change the allocation of the contiguous data space starting at the address *a-addr*<sub>1</sub>, previously allocated by [ALLOCATE](#) or [RESIZE](#), to *u* address units. *u* may be either larger or smaller than the current size of the region. The data-space pointer is unaffected by this operation.

If the operation succeeds, *a-addr*<sub>2</sub> is the aligned starting address of *u* address units of allocated memory and *ior* is zero. *a-addr*<sub>2</sub> may be, but need not be, the same as *a-addr*<sub>1</sub>. If they are not the same, the values contained in the region at *a-addr*<sub>1</sub> are copied to *a-addr*<sub>2</sub>, up to the minimum size of either of the two regions. If they are the same, the values contained in the region are preserved to the minimum of *u* or the original size. If *a-addr*<sub>2</sub> is not the same as *a-addr*<sub>1</sub>, the region of memory at *a-addr*<sub>1</sub> is returned to the system according to the operation of [FREE](#).

If the operation fails, *a-addr*<sub>2</sub> equals *a-addr*<sub>1</sub>, the region of memory at *a-addr*<sub>1</sub> is unaffected, and *ior* is the implementation-defined I/O result code.

See: [6.1.1650 HERE](#), [14.6.1.0707 ALLOCATE](#), [14.6.1.1605 FREE](#).

### 14.6.2 Memory-Allocation extension words

None

## 15 The optional Programming-Tools word set

### 15.1 Introduction

This optional word set contains words most often used during the development of applications.

### 15.2 Additional terms and notation

None.

### 15.3 Additional usage requirements

#### 15.3.1 Data types

A name token is a single-cell value that identifies a named word.

Append table 15.1 to table 3.1.

Table 15.1: Data types

<i>Symbol</i>	<i>Data type</i>	<i>Size on stack</i>
<i>nt</i>	name token	1 cell

See: [A.15.3.1 Name tokens](#).

#### 15.3.2 The Forth dictionary

A program using the words [CODE](#) or [; CODE](#) associated with assembler code has an environmental dependency on that particular instruction set and assembler notation.

Programs using the words [EDITOR](#) or [ASSEMBLER](#) require the Search Order word set or an equivalent implementation-defined capability.

See: [3.3 The Forth dictionary](#).

### 15.4 Additional documentation requirements

#### 15.4.1 System documentation

##### 15.4.1.1 Implementation-defined options

- ending sequence for input following [15.6.2.0470 ; CODE](#) and [15.6.2.0930 CODE](#);
- manner of processing input following [15.6.2.0470 ; CODE](#) and [15.6.2.0930 CODE](#);
- search-order capability for [15.6.2.1300 EDITOR](#) and [15.6.2.0740 ASSEMBLER](#) ([15.3.2 The Forth dictionary](#));
- source and format of display by [15.6.1.2194 SEE](#).

**15.4.1.2 Ambiguous conditions**

- deleting the compilation word-list ([15.6.2.1580](#) FORGET);
- fewer than  $u + 1$  items on control-flow stack ([15.6.2.1015](#) CS-PICK, [15.6.2.1020](#) CS-ROLL);
- *name* can't be found ([15.6.2.1580](#) FORGET, [15.6.2.2264](#) SYNONYM);
- *name* not defined via [6.1.1000](#) CREATE ([15.6.2.0470](#) ; CODE);
- [6.1.2033](#) POSTPONE applied to [15.6.2.2532](#) [IF];
- reaching the end of the input source before matching [15.6.2.2531](#) [ELSE] or [15.6.2.2533](#) [THEN] ([15.6.2.2532](#) [IF]);
- removing a needed definition ([15.6.2.1580](#) FORGET);
- [6.1.1710](#) IMMEDIATE is applied to a word defined by [15.6.2.2264](#) SYNONYM;
- [15.6.2.1940](#) NR> is used with data not stored by [15.6.2.1908](#) N>R;
- adding to or deleting from the wordlist during the execution of [15.6.2.2297](#) TRAVERSE-WORDLIST

**15.4.1.3 Other system documentation**

- no additional requirements.

**15.4.2 Program documentation****15.4.2.1 Environmental dependencies**

- using the words [15.6.2.0470](#) ; CODE or [15.6.2.0930](#) CODE.

**15.4.2.2 Other program documentation**

- no additional requirements.

**15.5 Compliance and labeling****15.5.1 Forth-2012 systems**

The phrase “Providing the Programming-Tools word set” shall be appended to the label of any Standard System that provides all of the Programming-Tools word set.

The phrase “Providing *name(s)* from the Programming-Tools Extensions word set” shall be appended to the label of any Standard System that provides portions of the Programming-Tools Extensions word set.

The phrase “Providing the Programming-Tools Extensions word set” shall be appended to the label of any Standard System that provides all of the Programming-Tools and Programming-Tools Extensions word sets.

**15.5.2 Forth-2012 programs**

The phrase “Requiring the Programming-Tools word set” shall be appended to the label of Standard Programs that require the system to provide the Programming-Tools word set.

**15.6.1.2194**    **SEE** TOOLS

( “*{spaces}name*” -- )

Display a human-readable representation of the named word’s definition. The source of the representation (object-code decompilation, source block, etc.) and the particular form of the display is implementation defined.

**SEE** may be implemented using pictured numeric output words. Consequently, its use may corrupt the transient region identified by **#>**.

See: [3.3.3.6 Other transient regions](#), [A.15.6.1.2194](#) **SEE**.

**15.6.1.2465**    **WORDS** TOOLS

( -- )

List the definition names in the first word list of the search order. The format of the display is implementation-dependent.

**WORDS** may be implemented using pictured numeric output words. Consequently, its use may corrupt the transient region identified by **#>**.

See: [3.3.3.6 Other transient regions](#), [A.15.6.1.2465](#) **WORDS**.

## 15.6.2 Programming-Tools extension words

**15.6.2.0470**    **;CODE** “semicolon-code” TOOLS EXT

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: *colon-sys* -- )

Append the run-time semantics below to the current definition. End the current definition, allow it to be found in the dictionary, and enter interpretation state, consuming *colon-sys*.

Subsequent characters in the parse area typically represent source code in a programming language, usually some form of assembly language. Those characters are processed in an implementation-defined manner, generating the corresponding machine code. The process continues, refilling the input buffer as needed, until an implementation-defined ending sequence is processed.

Run-time: ( -- ) ( R: *nest-sys* -- )

Replace the execution semantics of the most recent definition with the *name* execution semantics given below. Return control to the calling definition specified by *nest-sys*. An ambiguous condition exists if the most recent definition was not defined with **CREATE** or a user-defined word that calls **CREATE**.

*name* Execution: ( *i*\**x* -- *j*\**x* )

Perform the machine code sequence that was generated following **CODE**.

See: [6.1.1250 DOES>](#), [A.15.6.2.0470](#) ; **CODE**.

#### 15.6.2.0702 **AHEAD**

TOOLS EXT

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( C: -- *orig* )

Put the location of a new unresolved forward reference *orig* onto the control flow stack. Append the run-time semantics given below to the current definition. The semantics are incomplete until *orig* is resolved (e.g., by **THEN**).

Run-time: ( -- )

Continue execution at the location specified by the resolution of *orig*.

#### 15.6.2.0740 **ASSEMBLER**

TOOLS EXT

( -- )

Replace the first word list in the search order with the **ASSEMBLER** word list.

See: [16 The optional Search-Order word set](#).

#### 15.6.2.0830 **BYE**

TOOLS EXT

( -- )

Return control to the host operating system, if any.

#### 15.6.2.0930 **CODE**

TOOLS EXT

( “*{spaces}**name*” -- )

Skip leading space delimiters. Parse *name* delimited by a space. Create a definition for *name*, called a “code definition”, with the execution semantics defined below.

Subsequent characters in the parse area typically represent source code in a programming language, usually some form of assembly language. Those characters are processed in an implementation-defined manner, generating the corresponding machine code. The process continues, refilling the input buffer as needed, until an implementation-defined ending sequence is processed.

*name* Execution: ( *i*\**x* -- *j*\**x* )

Execute the machine code sequence that was generated following **CODE**.

See: [3.4.1 Parsing](#), [A.15.6.2.0930](#) **CODE**.

**15.6.2.1015 CS-PICK** “c-s-pick” TOOLS EXT

Interpretation: Interpretation semantics for this word are undefined.

Execution: ( C:  $dest_u \dots orig_0 \mid dest_0 -- dest_u \dots orig_0 \mid dest_0 dest_u$  ) ( S:  $u --$  )

Remove  $u$ . Copy  $dest_u$  to the top of the control-flow stack. An ambiguous condition exists if there are less than  $u+1$  items, each of which shall be an *orig* or *dest*, on the control-flow stack before **CS-PICK** is executed.

If the control-flow stack is implemented using the data stack,  $u$  shall be the topmost item on the data stack.

See: [A.15.6.2.1015 CS-PICK](#).

**15.6.2.1020 CS-ROLL** “c-s-roll” TOOLS EXT

Interpretation: Interpretation semantics for this word are undefined.

Execution: ( C:  $orig_u \mid dest_u orig_{u-1} \mid dest_{u-1} \dots orig_0 \mid dest_0 -- orig_{u-1} \mid dest_{u-1} \dots orig_0 \mid dest_0 orig_u \mid dest_u$  ) ( S:  $u --$  )

Remove  $u$ . Rotate  $u+1$  elements on top of the control-flow stack so that  $orig_u \mid dest_u$  is on top of the control-flow stack. An ambiguous condition exists if there are less than  $u+1$  items, each of which shall be an *orig* or *dest*, on the control-flow stack before **CS-ROLL** is executed.

If the control-flow stack is implemented using the data stack,  $u$  shall be the topmost item on the data stack.

See: [A.15.6.2.1020 CS-ROLL](#).

**15.6.2.1300 EDITOR** TOOLS EXT

(  $--$  )

Replace the first word list in the search order with the **EDITOR** word list.

See: [16 The optional Search-Order word set](#).

**15.6.2.1580 FORGET** TOOLS EXT

( “ $\langle spaces \rangle name$ ”  $--$  )

Skip leading space delimiters. Parse *name* delimited by a space. Find *name*, then delete *name* from the dictionary along with all words added to the dictionary after *name*. An ambiguous condition exists if *name* cannot be found.

If the Search-Order word set is present, **FORGET** searches the compilation word list. An ambiguous condition exists if the compilation word list is deleted.

An ambiguous condition exists if **FORGET** removes a word required for correct execution.

Note: This word is obsolescent and is included as a concession to existing implementations.

See: [3.4.1 Parsing](#), [A.15.6.2.1580 FORGET](#).

x:reset

**15.6.2.1908 N>R** “n-to-r” **TOOLS EXT**  
X:n-to-r

Interpretation: Interpretation semantics for this word are undefined.

Execution:  $(i * n + n -- ) (R: -- j * x + n)$

Remove  $n+1$  items from the data stack and store them for later retrieval by **NR>**. The return stack may be used to store the data. Until this data has been retrieved by **NR>**:

- this data will not be overwritten by a subsequent invocation of **N>R** and
- a program may not access data placed on the return stack before the invocation of **N>R**.

See: [15.6.2.1940 NR>](#), [A.15.6.2.1908 N>R](#).

x:reset

**15.6.2.1909.10 NAME>COMPILE** “name-to-compile” **TOOLS EXT**  
X:traverse-wordlist

$(nt -- xt)$

$xt$  represents the compilation semantics of the word  $nt$ . The returned  $xt$  has the stack effect  $(i * x x -- j * x)$ . Executing  $xt$  consumes  $x$  and performs the compilation semantics of the word represented by  $nt$ .

See: [A.15.6.2.1909.10 NAME>COMPILE](#), [15.6.2.2297 TRAVERSE-WORDLIST](#).

x:reset

**15.6.2.1909.20 NAME>INTERPRET** “name-to-interpret” **TOOLS EXT**  
X:traverse-wordlist

$(nt -- xt | 0)$

$xt$  represents the interpretation semantics of the word  $nt$ . If  $nt$  has no interpretation semantics, **NAME>INTERPRET** returns 0.

Note: This standard does not define the interpretation semantics of some words, but systems are allowed to do so.

See: [15.6.2.2297 TRAVERSE-WORDLIST](#).

x:reset

**15.6.2.1909.40 NAME>STRING** “name-to-string” **TOOLS EXT**  
X:traverse-wordlist

$(nt -- c-addr u)$

**NAME>STRING** returns the name of the word  $nt$  in the character string  $c-addr u$ . The case of the characters in the string is implementation-dependent. The buffer containing

*c-addr u* may be transient and valid until the next invocation of **NAME>STRING**. A program shall not write into the buffer containing the resulting string.

See: [15.6.2.2297 TRAVERSE-WORDLIST](#).

x:reset

**15.6.2.1940 NR>** “n-r-from” **TOOLS EXT**  
X:n-to-r

Interpretation: Interpretation semantics for this word are undefined.

Execution: ( -- *i\*x+n* ) ( R: *j\*x+n--* )

Retrieve the items previously stored by an invocation of **N>R**. *n* is the number of items placed on the data stack. It is an ambiguous condition if **NR>** is used with data not stored by **N>R**.

See: [15.6.2.1908 N>R](#), [A.15.6.2.1908 N>R](#).

**15.6.2.2250 STATE** **TOOLS EXT**

( -- *a-addr* )

Extend the semantics of [6.1.2250 STATE](#) to allow **;CODE** to change the value in **STATE**. A program shall not directly alter the contents of **STATE**.

See: [3.4 The Forth text interpreter](#), [6.1.0450 :](#), [6.1.0460 ;](#), [6.1.0670 ABORT](#), [6.1.2050 QUIT](#), [6.1.2250 STATE](#), [6.1.2500 \[](#), [6.1.2540 \]](#), [6.2.0455 :NONAME](#), [15.6.2.0470 ;CODE](#).

x:reset

**15.6.2.2264 SYNONYM** **TOOLS EXT**  
X:synonym

( “*{spaces}newname*” “*{spaces}oldname*” -- )

For both strings skip leading space delimiters. Parse *newname* and *oldname* delimited by a space. Create a definition for *newname* with the semantics defined below. *Newname* may be the same as *oldname*; when looking up *oldname*, *newname* shall not be found.

An ambiguous conditions exists if *oldname* can not be found or **IMMEDIATE** is applied to *newname*.

*newname* interpretation: ( *i\*x--j\*x* )

Perform the interpretation semantics of *oldname*.

*newname* compilation: ( *i\*x--j\*x* )

Perform the compilation semantics of *oldname*.

See: [6.1.1710 IMMEDIATE](#).

x:reset

**15.6.2.2297 TRVERSE-WORDLIST** TOOLS EXT  
X:traverse-wordlist

( *i \* x xt wid -- j \* x* )

Remove *wid* and *xt* from the stack. Execute *xt* once for every word in the wordlist *wid*, passing the name token *nt* of the word to *xt*, until the wordlist is exhausted or until *xt* returns false.

The invoked *xt* has the stack effect ( *k \* x nt -- l \* x flag* ) .

If *flag* is true, **TRVERSE-WORDLIST** will continue with the next name, otherwise it will return. **TRVERSE-WORDLIST** does not put any items other than *nt* on the stack when calling *xt*, so that *xt* can access and modify the rest of the stack.

**TRVERSE-WORDLIST** may visit words in any order, with one exception: words with the same name are called in the order newest-to-oldest (possibly with other words in between).

An ambiguous condition exists if words are added to or deleted from the wordlist *wid* during the execution of **TRVERSE-WORDLIST**.

See: [A.15.6.2.2297 TRVERSE-WORDLIST](#), [15.6.2.1909.40 NAME>STRING](#),  
[15.6.2.1909.20 NAME>INTERPRET](#), [15.6.2.1909.10 NAME>COMP ILE](#).

x:reset

**15.6.2.2530.30 [DEFINED]** “bracket-defined”  
TOOLS EXT  
X:defined

Compilation: Perform the execution semantics given below.

Execution: ( “*<spaces>name ...*” -- *flag* )

Skip leading space delimiters. Parse name delimited by a space. Return a true flag if *name* is the name of a word that can be found (according to the rules in the system’s **FIND**); otherwise return a false flag. **[DEFINED]** is an immediate word.

**15.6.2.2531 [ELSE]** “bracket-else”  
TOOLS EXT

Compilation: Perform the execution semantics given below.

Execution: ( “*<spaces>name ...*” -- )

Skipping leading spaces, parse and discard space-delimited words from the parse area, including nested occurrences of **[IF]** ... **[THEN]** and **[IF]** ... **[ELSE]** ... **[THEN]**, until the word **[THEN]** has been parsed and discarded. If the parse area becomes exhausted, it is refilled as with **REFILL**. **[ELSE]** is an immediate word.

See: [3.4.1 Parsing](#), [A.15.6.2.2531 \[ELSE\]](#).

**15.6.2.2532 [IF]** “bracket-if”  
TOOLS EXT

Compilation: Perform the execution semantics given below.

164 ! “ # \$ % & ’ ( ) \* + , - . / digits ; : < = > ? @ ALPHA [ \ ] ^ \_ ‘ alpha { | } ~ tools

Execution: (*flag* | *flag* “*<spaces>name ...*” -- )

If *flag* is true, do nothing. Otherwise, skipping leading spaces, parse and discard space-delimited words from the parse area, including nested occurrences of **[IF]** ... **[THEN]** and **[IF]** ... **[ELSE]** ... **[THEN]**, until either the word **[ELSE]** or the word **[THEN]** has been parsed and discarded. If the parse area becomes exhausted, it is refilled as with **REFILL**. **[IF]** is an immediate word.

An ambiguous condition exists if **[IF]** is **POSTPONED**, or if the end of the input buffer is reached and cannot be refilled before the terminating **[ELSE]** or **[THEN]** is parsed.

See: [3.4.1 Parsing](#), [A.15.6.2.2532](#) **[IF]**.

**15.6.2.2533**    **[THEN]**    “bracket-then”    TOOLS EXT

Compilation: Perform the execution semantics given below.

Execution: ( -- )

Does nothing. **[THEN]** is an immediate word.

See: [A.15.6.2.2533](#) **[THEN]**.

**15.6.2.2534**    **[UNDEFINED]**    “bracket-undefined”    TOOLS EXT  
x:reset  
\*:defined

Compilation: Perform the execution semantics given below.

Execution: ( “*<spaces>name ...*” -- *flag* )

Skip leading space delimiters. Parse name delimited by a space. Return a false flag if *name* is the name of a word that can be found (according to the rules in the system’s **FIND**); otherwise return a true flag. **[UNDEFINED]** is an immediate word.

## 16 The optional Search-Order word set

### 16.1 Introduction

### 16.2 Additional terms and notation

**compilation word list:** The word list into which new definition names are placed.

**search order:** A list of word lists specifying the order in which the dictionary will be searched.

### 16.3 Additional usage requirements

#### 16.3.1 Data types

Word list identifiers are implementation-dependent single-cell values that identify word lists.

Append table 16.1 to table 3.1.

Table 16.1: Data types

<i>Symbol</i>	<i>Data type</i>	<i>Size on stack</i>
<i>wid</i>	word list identifiers	1 cell

See: [3.1 Data types](#), [3.4.2 Finding definition names](#), [3.4 The Forth text interpreter](#).

#### 16.3.2 Environmental queries

Append table 16.2 to table 3.5.

See: [3.2.6 Environmental queries](#).

Table 16.2: Environmental Query Strings

String	Value data type	Constant?	Meaning
WORDLISTS	<i>n</i>	yes	maximum number of word lists usable in the search order

#### 16.3.3 Finding definition names

When searching a word list for a definition name, the system shall search each word list from its last definition to its first. The search may encompass only a single word list, as with [SEARCH-WORDLIST](#), or all the word lists in the search order, as with the text interpreter and [FIND](#).

Changing the search order shall only affect the subsequent finding of definition names in the dictionary. A system with the Search-Order word set shall allow at least eight word lists in the search order.

An ambiguous condition exists if a program changes the compilation word list during the compilation of a definition or before modification of the behavior of the most recently compiled definition with [;CODE](#), [DOES>](#), or [IMMEDIATE](#).

A program that requires more than eight word lists in the search order has an environmental dependency.

See: [3.4.2 Finding definition names](#).

### 16.3.4 Contiguous regions

The regions of data space produced by the operations described in [3.3.3.2 Contiguous regions](#) may be non-contiguous if `WORDLIST` is executed between allocations.

## 16.4 Additional documentation requirements

### 16.4.1 System documentation

#### 16.4.1.1 Implementation-defined options

- maximum number of word lists in the search order ([16.3.3 Finding definition names](#), [16.6.1.2197 SET-ORDER](#));
- minimum search order ([16.6.1.2197 SET-ORDER](#), [16.6.2.1965 ONLY](#)).

#### 16.4.1.2 Ambiguous conditions

- changing the compilation word list ([16.3.3 Finding definition names](#));
- search order empty ([16.6.2.2037 PREVIOUS](#));
- too many word lists in search order ([16.6.2.0715 ALSO](#)).

#### 16.4.1.3 Other system documentation

- no additional requirements.

### 16.4.2 Program documentation

#### 16.4.2.1 Environmental dependencies

- requiring more than eight word-lists in the search order ([16.3.3 Finding definition names](#)).

#### 16.4.2.2 Other program documentation

- no additional requirements.

## 16.5 Compliance and labeling

### 16.5.1 Forth-2012 systems

The phrase “Providing the Search-Order word set” shall be appended to the label of any Standard System that provides all of the Search-Order word set.

The phrase “Providing *name(s)* from the Search-Order Extensions word set” shall be appended to the label of any Standard System that provides portions of the Search-Order Extensions word set.

The phrase “Providing the Search-Order Extensions word set” shall be appended to the label of any Standard System that provides all of the Search-Order and Search-Order Extensions word sets.

## 16.5.2 Forth-2012 programs

The phrase “Requiring the Search-Order word set” shall be appended to the label of Standard Programs that require the system to provide the Search-Order word set.

The phrase “Requiring *name(s)* from the Search-Order Extensions word set” shall be appended to the label of Standard Programs that require the system to provide portions of the Search-Order Extensions word set.

The phrase “Requiring the Search-Order Extensions word set” shall be appended to the label of Standard Programs that require the system to provide all of the Search-Order and Search-Order Extensions word sets.

## 16.6 Glossary

### 16.6.1 Search-Order words

**16.6.1.1180 DEFINITIONS** SEARCH

( -- )

Make the compilation word list the same as the first word list in the search order. Specifies that the names of subsequent definitions will be placed in the compilation word list. Subsequent changes in the search order will not affect the compilation word list.

See: [16.3.3 Finding definition names](#).

**16.6.1.1550 FIND** SEARCH

Extend the semantics of [6.1.1550 FIND](#) to be:

( *c-addr* -- *c-addr* 0 | *xt* 1 | *xt* -1 )

Find the definition named in the counted string at *c-addr*. If the definition is not found after searching all the word lists in the search order, return *c-addr* and zero. If the definition is found, return *xt*. If the definition is immediate, also return one (*I*); otherwise also return minus-one (*-I*). For a given string, the values returned by **FIND** while compiling may differ from those returned while not compiling.

See: [3.4.2 Finding definition names](#), [6.1.0070 ' ,](#) [6.1.1550 FIND](#), [6.1.2033 POSTPONE](#), [6.1.2510 \[ ' \]](#).

**16.6.1.1595 FORTH-WORDLIST** SEARCH

( -- *wid* )

Return *wid*, the identifier of the word list that includes all standard words provided by the implementation. This word list is initially the compilation word list and is part of the initial search order.

**16.6.1.1643 GET-CURRENT** SEARCH

( -- *wid* )

Return *wid*, the identifier of the compilation word list.

**16.6.1.1647 GET-ORDER** SEARCH

( -- *wid<sub>n</sub> ... wid<sub>1</sub> n* )

Returns the number of word lists *n* in the search order and the word list identifiers *wid<sub>n</sub> ... wid<sub>1</sub>* identifying these word lists. *wid<sub>1</sub>* identifies the word list that is searched first, and *wid<sub>n</sub>* the word list that is searched last. The search order is unaffected.

**16.6.1.2192 SEARCH-WORDLIST** SEARCH

( *c-addr u wid* -- 0 | *xt 1* | *xt -1* )

Find the definition identified by the string *c-addr u* in the word list identified by *wid*. If the definition is not found, return zero. If the definition is found, return its execution token *xt* and one (*1*) if the definition is immediate, minus-one (*-1*) otherwise.

See: [A.16.6.1.2192 SEARCH-WORDLIST](#).

**16.6.1.2195 SET-CURRENT** SEARCH

( *wid* -- )

Set the compilation word list to the word list identified by *wid*.

**16.6.1.2197 SET-ORDER** SEARCH

( *wid<sub>n</sub> ... wid<sub>1</sub> n* -- )

Set the search order to the word lists identified by *wid<sub>n</sub> ... wid<sub>1</sub>*. Subsequently, word list *wid<sub>1</sub>* will be searched first, and word list *wid<sub>n</sub>* searched last. If *n* is zero, empty the search order. If *n* is minus one, set the search order to the implementation-defined minimum search order. The minimum search order shall include the words [FORTH-WORDLIST](#) and [SET-ORDER](#). A system shall allow *n* to be at least eight.

**16.6.1.2460 WORDLIST** SEARCH

( -- *wid* )

Create a new empty word list, returning its word list identifier *wid*. The new word list may be returned from a pool of preallocated word lists or may be dynamically allocated in data space. A system shall allow the creation of at least 8 new word lists in addition to any provided as part of the system.

**16.6.2 Search-Order extension words****16.6.2.0715 ALSO** SEARCH EXT

( -- )

Transform the search order consisting of  $wid_n, \dots, wid_2, wid_1$  (where  $wid_1$  is searched first) into  $wid_n, \dots, wid_2, wid_1, wid_1$ . An ambiguous condition exists if there are too many word lists in the search order.

**16.6.2.1590 FORTH** SEARCH EXT

( -- )

Transform the search order consisting of  $wid_n, \dots, wid_2, wid_1$  (where  $wid_1$  is searched first) into  $wid_n, \dots, wid_2, wid_{\text{FORTH-WORDLIST}}$ .

**16.6.2.1965 ONLY** SEARCH EXT

( -- )

Set the search order to the implementation-defined minimum search order. The minimum search order shall include the words **FORTH-WORDLIST** and **SET-ORDER**.

**16.6.2.1985 ORDER** SEARCH EXT

( -- )

Display the word lists in the search order in their search order sequence, from first searched to last searched. Also display the word list into which new definitions will be placed. The display format is implementation dependent.

**ORDER** may be implemented using pictured numeric output words. Consequently, its use may corrupt the transient region identified by **#>**.

See: [3.3.3.6 Other transient regions](#).

**16.6.2.2037 PREVIOUS** SEARCH EXT

( -- )

Transform the search order consisting of  $wid_n, \dots, wid_2, wid_1$  (where  $wid_1$  is searched first) into  $wid_n, \dots, wid_2$ . An ambiguous condition exists if the search order was empty before **PREVIOUS** was executed.

## 17 The optional String word set

### 17.1 Introduction

### 17.2 Additional terms and notation

None.

### 17.3 Additional usage requirements

None.

### 17.4 Additional documentation requirements

#### 17.4.1 System documentation

##### 17.4.1.1 Implementation-defined options

- no additional options.

##### 17.4.1.2 Ambiguous conditions

- The substitution cannot be created (**REPLACES**);
- The name of a substitution contains the ‘%’ delimiter character (**REPLACES**);
- Result of a substitution is too long to fit into the given buffer (**SUBSTITUTE** and **UNESCAPE**);
- Source and destination buffers for **SUBSTITUTE** are the same.

##### 17.4.1.3 Other system documentation

- no additional requirements.

#### 17.4.2 Program documentation

##### 17.4.2.1 Environmental dependencies

- no additional dependencies.

##### 17.4.2.2 Other program documentation

- no additional requirements.

### 17.5 Compliance and labeling

#### 17.5.1 Forth-2012 systems

The phrase “Providing the String word set” shall be appended to the label of any Standard System that provides all of the String word set.

**17.6.1.0910 CMOVE** “c-move” STRING

( *c-addr*<sub>1</sub> *c-addr*<sub>2</sub> *u* -- )

If *u* is greater than zero, copy *u* consecutive characters from the data space starting at *c-addr*<sub>1</sub> to that starting at *c-addr*<sub>2</sub>, proceeding character-by-character from lower addresses to higher addresses.

See: [17.6.1.0920 CMOVE>](#), [A.17.6.1.0910 CMOVE](#).

**17.6.1.0920 CMOVE>** “c-move-up” STRING

( *c-addr*<sub>1</sub> *c-addr*<sub>2</sub> *u* -- )

If *u* is greater than zero, copy *u* consecutive characters from the data space starting at *c-addr*<sub>1</sub> to that starting at *c-addr*<sub>2</sub>, proceeding character-by-character from higher addresses to lower addresses.

See: [17.6.1.0910 CMOVE](#), [A.17.6.1.0920 CMOVE>](#).

**17.6.1.0935 COMPARE** STRING

( *c-addr*<sub>1</sub> *u*<sub>1</sub> *c-addr*<sub>2</sub> *u*<sub>2</sub> -- *n* )

Compare the string specified by *c-addr*<sub>1</sub> *u*<sub>1</sub> to the string specified by *c-addr*<sub>2</sub> *u*<sub>2</sub>. The strings are compared, beginning at the given addresses, character by character, up to the length of the shorter string or until a difference is found. If the two strings are identical, *n* is zero. If the two strings are identical up to the length of the shorter string, *n* is minus-one (-1) if *u*<sub>1</sub> is less than *u*<sub>2</sub> and one (1) otherwise. If the two strings are not identical up to the length of the shorter string, *n* is minus-one (-1) if the first non-matching character in the string specified by *c-addr*<sub>1</sub> *u*<sub>1</sub> has a lesser numeric value than the corresponding character in the string specified by *c-addr*<sub>2</sub> *u*<sub>2</sub> and one (1) otherwise.

**17.6.1.2191 SEARCH** STRING

( *c-addr*<sub>1</sub> *u*<sub>1</sub> *c-addr*<sub>2</sub> *u*<sub>2</sub> -- *c-addr*<sub>3</sub> *u*<sub>3</sub> *flag* )

Search the string specified by *c-addr*<sub>1</sub> *u*<sub>1</sub> for the string specified by *c-addr*<sub>2</sub> *u*<sub>2</sub>. If *flag* is true, a match was found at *c-addr*<sub>3</sub> with *u*<sub>3</sub> characters remaining. If *flag* is false there was no match and *c-addr*<sub>3</sub> is *c-addr*<sub>1</sub> and *u*<sub>3</sub> is *u*<sub>1</sub>.

**17.6.1.2212 SLITERAL** STRING

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( *c-addr*<sub>1</sub> *u* -- )

Append the run-time semantics given below to the current definition.

Run-time: ( -- *c-addr<sub>2</sub> u* )

Return *c-addr<sub>2</sub> u* describing a string consisting of the characters specified by *c-addr<sub>1</sub> u* during compilation. A program shall not alter the returned string.

See: [A.17.6.1.2212 SLITERAL](#).

## 17.6.2 String extension words

### 17.6.2.2141 REPLACES

STRING EXT  
X:substitute

( *c-addr<sub>1</sub> u<sub>1</sub> c-addr<sub>2</sub> u<sub>2</sub> --* )

Set the string *c-addr<sub>1</sub> u<sub>1</sub>* as the text to substitute for the substitution named by *c-addr<sub>2</sub> u<sub>2</sub>*. If the substitution does not exist it is created. The program may then reuse the buffer *c-addr<sub>1</sub> u<sub>1</sub>* without affecting the definition of the substitution.

Ambiguous conditions occur as follows:

- The substitution cannot be created;
- The name of a substitution contains the ‘%’ delimiter character.

**REPLACES** may allot data space and create a definition. This breaks the contiguity of the current region and is not allowed during compilation of a colon definition

See: [3.3.3.2 Contiguous regions](#), [3.4.5 Compilation](#), [17.6.2.2255 SUBSTITUTE](#).

### 17.6.2.2255 SUBSTITUTE

STRING EXT  
X:substitute

( *c-addr<sub>1</sub> u<sub>1</sub> c-addr<sub>2</sub> u<sub>2</sub> -- c-addr<sub>2</sub> u<sub>3</sub> n* )

Perform substitution on the string *c-addr<sub>1</sub> u<sub>1</sub>* placing the result at string *c-addr<sub>2</sub> u<sub>3</sub>*, where *u<sub>3</sub>* is the length of the resulting string. An error occurs if the resulting string will not fit into *c-addr<sub>2</sub> u<sub>2</sub>* or if *c-addr<sub>2</sub>* is the same as *c-addr<sub>1</sub>*. The return value *n* is positive or 0 on success and indicates the number of substitutions made. A negative value for *n* indicates that an error occurred, leaving *c-addr<sub>2</sub> u<sub>3</sub>* undefined. Negative values of *n* are implementation defined except for values in table [9.1 THROW code assignments](#).

Substitution occurs left to right from the start of *c-addr<sub>1</sub>* in one pass and is non-recursive.

When text of a potential substitution name, surrounded by ‘%’ (ASCII \$25) delimiters is encountered by **SUBSTITUTE**, the following occurs:

- a) If the name is null, a single delimiter character is passed to the output, i.e., %% is replaced by %. The current number of substitutions is not changed.
- b) If the text is a valid substitution name acceptable to [17.6.2.2141 REPLACES](#), the leading and trailing delimiter characters and the enclosed substitution name are replaced by the substitution text. The current number of substitutions is incremented.

- c) If the text is not a valid substitution name, the name with leading and trailing delimiters is passed unchanged to the output. The current number of substitutions is not changed.
- d) Parsing of the input string resumes after the trailing delimiter.

If after processing any pairs of delimiters, the residue of the input string contains a single delimiter, the residue is passed unchanged to the output.

See: [17.6.2.2141 REPLACES](#), [17.6.2.2375 UNESCAPE](#), [A.17.6.2.2255 SUBSTITUTE](#).

### 17.6.2.2375 UNESCAPE

STRING EXT  
X:substitute

( *c-addr<sub>1</sub> u<sub>1</sub> c-addr<sub>2</sub> -- c-addr<sub>2</sub> u<sub>2</sub>*  )

Replace each ‘%’ character in the input string *c-addr<sub>1</sub> u<sub>1</sub>* by two ‘%’ characters. The output is represented by *c-addr<sub>2</sub> u<sub>2</sub>*. The buffer at *c-addr<sub>2</sub>* shall be big enough to hold the unescaped string. An ambiguous condition occurs if the resulting string will not fit into the destination buffer (*c-addr<sub>2</sub>*).

See: [17.6.2.2255 SUBSTITUTE](#).

x:reset

## 18 The optional Extended-Character word set

### 18.1 Introduction

This word set deals with variable width character encodings. It also works with fixed width encodings.

Since the standard specifies ASCII encoding for characters, only ASCII-compatible encodings may be used. Because ASCII compatibility has so many benefits, most encodings actually are ASCII compatible. The characters beyond the ASCII encoding are called “extended characters” (xchars).

All words dealing with strings shall handle xchars when the xchar word set is present. This includes dictionary definitions. White space parsing does not have to treat code points greater than \$20 as white space.

### 18.2 Additional terms and notation

#### 18.2.1 Definition of Terms

**code point:** A member of an extended character set.

#### 18.2.2 Parsed-text notation

Append table 18.1 to table 2.1.

Table 18.1: Parsed text abbreviations

<i>Abbreviation</i>	<i>Description</i>
<i>&lt;xchar&gt;</i>	the delimiting extended character

See: [2.2.3 Parsed-text notation](#).

### 18.3 Additional usage requirements

#### 18.3.1 Data types

Append table 18.2 to table 3.1.

Table 18.2: Data Types

<i>Symbol</i>	<i>Data type</i>	<i>Size on stack</i>
<i>pchar</i>	primitive character	1 cell
<i>xchar</i>	extended character	1 cell
<i>xc-addr</i>	xchar-aligned address	1 cell

See: [3.1 Data types](#).

### 18.3.1.1 Extended Characters

An extended character (*xchar*) is the code point of a character within an extended character set; on the stack it is a subset of *u*. Extended characters are stored in memory encoded as one or more primitive characters (*pchars*).

### 18.3.2 Environmental queries

Append table 18.3 to table 3.5.

Table 18.3: Environmental Query Strings

String	Value data type	Constant?	Meaning
XCHAR-ENCODING	<i>c-addr u</i>	no	Returns a printable ASCII string that represents the encoding, and use the preferred MIME name (if any) or the name in the IANA character-set register <sup>1</sup> (RFC-1700) such as “ISO-LATIN-1” or “UTF-8”, with the exception of “ASCII”, where the alias “ASCII” is preferred.
MAX-XCHAR	<i>u</i>	no	Maximal value for <i>xchar</i>
XCHAR-MAXMEM	<i>u</i>	no	Maximal memory consumed by an <i>xchar</i> in address units

<sup>1</sup> <http://www.iana.org/assignments/character-sets>

See: 3.2.6 Environmental queries.

### 18.3.3 Common encodings

Input and files are often encoded iso-latin-1 or utf-8. The encoding depends on settings of the computer system such as the LANG environment variable on Unix. You can use the system consistently only when you do not change the encoding, or only use the ASCII subset. The typical practice in environments requiring more than one encoding is that the base system is ASCII only, and the character set is then extended to specify the required encoding.

### 18.3.4 The Forth text interpreter

In section 3.4.1.3 Text interpreter input number conversion,  $\langle cnum \rangle$  should be redefined to be:

$\langle cnum \rangle$  the number is the value of  $\langle xchar \rangle$

### 18.3.5 Input and Output

IO words such as **KEY**, **EMIT**, **TYPE**, **READ-FILE**, **READ-LINE**, **WRITE-FILE**, and **WRITE-LINE** operate on *pchars*. Therefore, it is possible that these words read or write incomplete *xchars*, which are completed in the next consecutive operation(s). The IO system shall combine these *pchars* into a complete *xchars* on output, or split an *xchars* into *pchars* on input, and shall not throw a “malformed *xchars*” exception when the combination of these *pchars* form a valid *xchars*. **-TRAILING-GARBAGE** can be used to process an incomplete *xchars* at the end of such an IO operation.

**ACCEPT** as input editor may be aware of *xchars* to provide comfort like backspace or cursor movement.

## 18.4 Additional documentation requirements

### 18.4.1 System documentation

#### 18.4.1.1 Implementation-defined options

Since Unicode input and display poses a number of challenges like input method editors for different languages, left-to-right and right-to-left writing, and most fonts contain only a subset of Unicode glyphs, systems should document their capabilities. File IO and in-memory string handling should work transparently with *xchars*.

#### 18.4.1.2 Ambiguous conditions

- the data in memory does not encode a valid xchar (**18.6.1.2486.50 X-SIZE**);
- the *xchars* value is outside the range of allowed code points of the current character set used;
- words improperly used outside **6.1.0490 <#** and **6.1.0040 #>** (**18.6.2.2488.20 XHOLD**).

#### 18.4.1.3 Other system documentation

- no additional requirements.

### 18.4.2 Program documentation

- no additional requirements.

## 18.5 Compliance and labeling

### 18.5.1 Forth-2012 systems

The phrase “Providing the Extended-Character word set” shall be appended to the label of any Standard System that provides all of the Extended-Character word set.

The phrase “Providing *name(s)* from the Extended-Character Extensions word set” shall be appended to the label of any Standard System that provides portions of the Extended-Character Extensions word set.

The phrase “Providing the Extended-Character Extensions word set” shall be appended to the label of any Standard System that provides all of the Extended-Character and Extended-Character Extensions word sets.

### 18.5.2 Forth-2012 programs

The phrase “Requiring the Extended-Character word set” shall be appended to the label of Standard Programs that require the system to provide the Extended-Character word set.

The phrase “Requiring *name(s)* from the Extended-Character Extensions word set” shall be appended to the label of Standard Programs that require the system to provide portions of the Extended-Character Extensions word set.

The phrase “Requiring the Extended-Character Extensions word set” shall be appended to the label of Standard Programs that require the system to provide all of the Extended-Character Exception and Extended-Character Extensions word sets.

## 18.6 Glossary

### 18.6.1 Extended-Character words

#### 18.6.1.2486.50 X-SIZE

XCHAR  
X:xchar

( *xc-addr* *u*<sub>1</sub> -- *u*<sub>2</sub> )

*u*<sub>2</sub> is the number of pchars used to encode the first xchar stored in the string *xc-addr* *u*<sub>1</sub>. To calculate the size of the xchar, only the bytes inside the buffer may be accessed. An ambiguous condition exists if the xchar is incomplete or malformed.

#### 18.6.1.2487.10 XC!+

“x-c-store-plus”

XCHAR  
X:xchar

( *xchar* *xc-addr*<sub>1</sub> -- *xc-addr*<sub>2</sub> )

Stores the *xchar* at *xc-addr*<sub>1</sub>. *xc-addr*<sub>2</sub> points to the first memory location after the stored *xchar*.

#### 18.6.1.2487.15 XC!+?

“x-c-store-plus-query”

XCHAR  
X:xchar

( *xchar* *xc-addr*<sub>1</sub> *u*<sub>1</sub> -- *xc-addr*<sub>2</sub> *u*<sub>2</sub> *flag* )

Stores the *xchar* into the string buffer specified by *xc-addr*<sub>1</sub> *u*<sub>1</sub>. *xc-addr*<sub>2</sub> *u*<sub>2</sub> is the remaining string buffer. If the *xchar* did fit into the buffer, *flag* is true, otherwise *flag* is false, and *xc-addr*<sub>2</sub> *u*<sub>2</sub> equal *xc-addr*<sub>1</sub> *u*<sub>1</sub>. **XC!+?** is safe for buffer overflows.

#### 18.6.1.2487.20 XC,

“x-c-comma”

XCHAR  
X:xchar

( *xchar* -- )

Append the encoding of *xchar* to the dictionary.

See: [6.1.0860 C,](#)

#### 18.6.1.2487.25 XC-SIZE

“x-c-size”

XCHAR  
X:xchar

( *xchar* -- *u* )

*u* is the number of pchars used to encode *xchar* in memory.

**18.6.1.2487.35 XC@+** “x-c-fetch-plus” XCHAR  
X:xchar

( *xc-addr<sub>1</sub>* -- *xc-addr<sub>2</sub>* *xchar* )

Fetches the *xchar* at *xc-addr<sub>1</sub>*. *xc-addr<sub>2</sub>* points to the first memory location after the retrieved *xchar*.

x.reset

**18.6.1.2487.40 XCHAR+** “x-char-plus” XCHAR  
X:xchar

( *xc-addr<sub>1</sub>* -- *xc-addr<sub>2</sub>* )

Adds the size of the *xchar* stored at *xc-addr<sub>1</sub>* to this address, giving *xc-addr<sub>2</sub>*.

See: [6.1.0897 CHAR+](#).

x.reset

**18.6.1.2488.10 XEMIT** “x-emit” XCHAR  
X:xchar

( *xchar* -- )

Prints an *xchar* on the terminal.

See: [6.1.1320 EMIT](#)

x.reset

**18.6.1.2488.30 XKEY** “x-key” XCHAR  
X:xchar

( -- *xchar* )

Reads an *xchar* from the terminal. This will discard all input events up to the completion of the *xchar*.

See: [6.1.1750 KEY](#).

x.reset

**18.6.1.2488.35 XKEY?** “x-key-query” XCHAR  
X:xchar

( -- *flag* )

*Flag* is true when it’s possible to do [XKEY](#) without blocking. Subsequent [KEY?](#), [KEY](#), [EKEY?](#), and [EKEY](#) may be affected by [XKEY?](#).

See: [10.6.1.1755 KEY?](#).

x.reset

## 18.6.2 Extended-Character extension words

**18.6.2.0145 +X/STRING** “plus-x-string” XCHAR EXT  
X:xchar

( *xc-addr<sub>1</sub>* *u<sub>1</sub>* -- *xc-addr<sub>2</sub>* *u<sub>2</sub>* )

Step forward by one *xchar* in the buffer defined by *xc-addr<sub>1</sub>* *u<sub>1</sub>*. *xc-addr<sub>2</sub>* *u<sub>2</sub>* is the remaining buffer after stepping over the first *xchar* in the buffer.

x.reset

**18.6.2.2487.30 XC-WIDTH** “x-c-width” XCHAR EXT  
X:xchar

( *xchar* -- *n* )

*n* is the number of monospace ASCII characters that take the same space to display as the *xchar*; i.e., *xchar* width is always an integer multiple of the width of an ASCII char.

x.reset

**18.6.2.2487.45 XCHAR-** “x-char-minus” XCHAR EXT  
X:xchar

( *xc-addr*<sub>1</sub> -- *xc-addr*<sub>2</sub> )

Goes backward from *xc-addr*<sub>1</sub> until it finds an xchar so that the size of this xchar added to *xc-addr*<sub>2</sub> gives *xc-addr*<sub>1</sub>. There is an ambiguous condition when the encoding doesn't permit reliable backward stepping through the text.

x.reset

**18.6.2.2488.20 XHOLD** “x-hold” XCHAR EXT  
X:xchar

( *xchar* -- )

Adds *xchar* to the picture numeric output string. An ambiguous condition exists if **XHOLD** executes outside of a **<# #>** delimited number conversion.

See: [6.1.1670 HOLD](#).

x.reset

**18.6.2.2495 X\STRING-** “x-string-minus” XCHAR EXT  
X:xchar

( *xc-addr* *u*<sub>1</sub> -- *xc-addr* *u*<sub>2</sub> )

Search for the penultimate xchar in the string *xc-addr* *u*<sub>1</sub>. The string *xc-addr* *u*<sub>2</sub> contains all xchars of *xc-addr* *u*<sub>1</sub>, but the last. Unlike **XCHAR-**, **X\STRING-** can be implemented in encodings where xchar boundaries can only reliably detected when scanning in forward direction.

x.reset

**18.6.2.2520 [CHAR]** “bracket-char” XCHAR EXT  
X:xchar

Interpretation: Interpretation semantics for this word are undefined.

Compilation: ( “{*spaces*}*name*” -- )

Skip leading space delimiters. Parse *name* delimited by a space. Append the run-time semantics given below to the current definition.

Run-time: ( -- *xchar* )

Place *xchar*, the value of the first xchar of *name*, on the stack.

See: [6.1.2520 \[CHAR\]](#)

## **Annex A**

### (informative)

### **Rationale**

## **A.1 Introduction**

### **A.1.1 Purpose**

### **A.1.2 Scope**

When judging relative merits of proposed changes to the standard, the members of the committee were guided by the following goals (listed in alphabetic order):

Consistency	The standard provides a functionally complete set of words with minimal functional overlap.
Cost of compliance	This goal includes such issues as common practice, how much existing code would be broken by the proposed change, and the amount of effort required to bring existing applications and systems into conformity with the standard.
Efficiency	Execution speed, memory compactness.
Portability	Words chosen for inclusion should be free of system-dependent features.
Readability	Forth definition names should clearly delineate their behavior. That behavior should have an apparent simplicity which supports rapid understanding. Forth should be easily taught and support readily maintained code.
Utility	Be judged to have sufficiently essential functionality and frequency of use to be deemed suitable for inclusion.

## **A.2 Terms and notation**

### **A.2.1 Definitions of terms**

#### **aligned**

Data can only be loaded from and stored to addresses that are aligned according to the alignment requirements of the accessed type. Field offsets that are added to structure addresses also need to be aligned.

#### **ambiguous condition**

The response of a Standard System to an ambiguous condition is left to the discretion of the implementor. A Standard System need not explicitly detect or report the occurrence of ambiguous conditions.

#### **cross compiler**

Cross compilers may be used to prepare a program for execution in an embedded system, or may be used to generate Forth kernels either for the same or a different run-time environment.

## data field

In earlier standards, data fields were known as “parameter fields”.

On subroutine threaded Forth systems, everything is object code. There are no traditional code or data fields. Only a word defined by **CREATE** or by a word that calls **CREATE** has a data field. Only a data field defined via **CREATE** can be manipulated portably.

## word set

This standard recognizes that some functions, while useful in certain application areas, are not sufficiently general to justify requiring them in all Forth systems. Further, it is helpful to group Forth words according to related functions. These issues are dealt with using the concept of word sets.

The “Core” word set contains the essential body of words in a Forth system. It is the only “required” word set. Other word sets defined in this standard are optional additions to make it possible to provide Standard Systems with tailored levels of functionality.

## A.2.2 Notation

### A.2.2.2 Stack notation

The use of *-sys*, *orig*, and *dest* data types in stack effect diagrams conveys two pieces of information. First, it warns the reader that many implementations use the data stack in unspecified ways for those purposes, so that items underneath on either the control-flow or data stacks are unavailable. Second, in cases where *orig* and *dest* are used, explicit pairing rules are documented on the assumption that all systems will implement that model so that its results are equivalent to employment of some stack, and that in fact many implementations do use the data stack for this purpose. However, nothing in this standard requires that implementations actually employ the data stack (or any other) for this purpose so long as the implied behavior of the model is maintained.

## A.3 Usage requirements

Forth systems are unusually simple to develop, in comparison with compilers for more conventional languages such as C. In addition to Forth systems supported by vendors, public-domain implementations and implementation guides have been widely available for nearly twenty years, and a large number of individuals have developed their own Forth systems. As a result, a variety of implementation approaches have developed, each optimized for a particular platform or target market.

The committee has endeavored to accommodate this diversity by constraining implementors as little as possible, consistent with a goal of defining a standard interface between an underlying Forth System and an application program being developed on it.

Similarly, we will not undertake in this section to tell you how to implement a Forth System, but rather will provide some guidance as to what the minimum requirements are for systems that can properly claim compliance with this standard.

### A.3.1 Data types

Most computers deal with arbitrary bit patterns. There is no way to determine by inspection whether a cell contains an address or an unsigned integer. The only meaning a datum possesses is the meaning assigned

by an application.

When data are operated upon, the meaning of the result depends on the meaning assigned to the input values. Some combinations of input values produce meaningless results: for instance, what meaning can be assigned to the arithmetic sum of the ASCII representation of the character “A” and a TRUE flag? The answer may be “no meaning”; or alternatively, that operation might be the first step in producing a checksum. Context is the determiner.

The discipline of circumscribing meaning which a program may assign to various combinations of bit patterns is sometimes called *data typing*. Many computer languages impose explicit data typing and have compilers that prevent ill-defined operations.

Forth rarely explicitly imposes data-type restrictions. Still, data types implicitly do exist, and discipline is required, particularly if portability of programs is a goal. In Forth, it is incumbent upon the programmer (rather than the compiler) to determine that data are accurately typed.

This section attempts to offer guidance regarding *de facto* data typing in Forth.

### A.3.1.2 Character types

The correct identification and proper manipulation of the character data type is beyond the purview of Forth’s enforcement of data type by means of stack depth. Characters do not necessarily occupy the entire width of their single stack entry with meaningful data. While the distinction between signed and unsigned character is entirely absent from the formal specification of Forth, the tendency in practice is to treat characters as short positive integers when mathematical operations come into play.

#### a) Standard Character Set

- 1) The storage unit for the character data type (**C@**, **C!**, **FILL**, etc.) must be able to contain unsigned numbers from 0 through 255.
- 2) An implementation is not required to restrict character storage to that range, but a Standard Program without environmental dependencies cannot assume the ability to store numbers outside that range in a “char” location.
- 3) Since a “char” can store small positive numbers and since the character data type is a sub-range of the unsigned integer data type, **C!** must store the  $n$  least-significant bits of a cell ( $8 \leq n \leq \text{bits/cell}$ ). Given the enumeration of allowed number representations and their known encodings, “**TRUE** **xx C!** **xx C@**” must leave a stack item with some number of bits set, which will thus will be accepted as non-zero by **IF**.
- 4) For the purposes of input (**KEY**, **ACCEPT**, etc.) and output (**EMIT**, **TYPE**, etc.), the encoding between numbers and human-readable symbols is ISO646/IRV (ASCII) within the range from 32 to 126 (space to ~). Outside that range, it is up to the implementation. The obvious implementation choice is to use ASCII control characters for the range from 0 to 31, at least for the “displayable” characters in that range (TAB, RETURN, LINEFEED, FORMFEED). However, this is not as clear-cut as it may seem, because of the variation between operating systems on the treatment of those characters. For example, some systems TAB to 4 character boundaries, others to 8 character boundaries, and others to preset tab stops. Some systems perform an automatic linefeed after a carriage return, others perform an automatic carriage return after a linefeed, and others do neither.

The codes from 128 to 255 may eventually be standardized, either formally or informally, for use as international characters, such as the letters with diacritical marks found in many European languages. One such encoding is the 8-bit ISO Latin-1 character set. The computer marketplace at large will eventually decide which encoding set of those characters prevails. For Forth implementations running under an operating system (the majority of those running on standard platforms these days), most Forth implementors will probably choose to do whatever the system does, without performing any remapping within the domain of the Forth system itself.

- 5) A Standard Program can depend on the ability to receive any character in the range 32 ... 126 through **KEY**, and similarly to display the same set of characters with **EMIT**. If a program must be able to receive or display any particular character outside that range, it can declare an environmental dependency on the ability to receive or display that character.
- 6) A Standard Program cannot use control characters in definition names. However, a Standard System is not required to enforce this prohibition. Thus, existing systems that currently allow control characters in words names from **BLOCK** source may continue to allow them, and programs running on those systems will continue to work. In text file source, the parsing action with space as a delimiter (e.g., **BL WORD**) treats control characters the same as spaces. This effectively implies that you cannot use control characters in definition names from text-file source, since the text interpreter will treat the control characters as delimiters. Note that this “control-character folding” applies only when space is the delimiter, thus the phrase “**CHAR ) WORD**” may collect a string containing control characters.

#### b) Storage and retrieval

Characters are transferred from the data stack to memory by **C!** and from memory to the data stack by **C@**. A number of lower-significance bits equivalent to the implementation-dependent width of a *character* are transferred from a popped data stack entry to an address by the action of **C!** without affecting any bits which may comprise the higher-significance portion of the cell at the destination address; however, the action of **C@** clears all higher-significance bits of the data stack entry which it pushes that are beyond the implementation-dependent width of a character (which may include implementation-defined display information in the higher-significance bits). The programmer should keep in mind that operating upon arbitrary stack entries with words intended for the character data type may result in truncation of such data.

#### c) Manipulation on the stack

In addition to **C@** and **C!**, characters are moved to, from and upon the data stack by the following words:

```
>R ?DUP DROP DUP OVER PICK R> R@ ROLL ROT SWAP
```

#### d) Additional operations

The following mathematical operators are valid for character data:

`+ - * / /MOD MOD`

The following comparison and bitwise operators may be valid for characters, keeping in mind that display information cached in the most significant bits of characters in an implementation-defined fashion may have to be masked or otherwise dealt with:

`AND OR > < U> U< = <> 0= 0<> MAX MIN LSHIFT RSHIFT`

#### A.3.1.3 Single-cell types

A single-cell stack entry viewed without regard to typing is the fundamental data type of Forth. All other data types are actually represented by one or more single-cell stack entries.

##### a) Storage and retrieval

Single-cell data are transferred from the stack to memory by `!`; from memory to the stack by `@`. All bits are transferred in both directions and no type checking of any sort is performed, nor does the Standard System check that a memory address used by `!` or `@` is properly aligned or properly sized to hold the datum thus transferred.

##### b) Manipulation on the stack

Here is a selection of the most important words which move single-cell data to, from and upon the data stack:

`! @ >R ?DUP DROP DUP OVER PICK R> R@ ROLL ROT SWAP`

##### c) Comparison operators

The following comparison operators are universally valid for one or more single cells:

`= <> 0= 0<>`

#### A.3.1.3.1 Flags

A **FALSE** flag is a single-cell datum with all bits unset, and a **TRUE** flag is a single-cell datum with all bits set. While Forth words which test flags accept any non-null bit pattern as true, there exists the concept of the *well-formed flag*. If an operation whose result is to be used as a flag may produce any bit-mask other than **TRUE** or **FALSE**, the recommended discipline is to convert the result to a well-formed flag by means of the Forth word `0<>` so that the result of any subsequent logical operations on the flag will be predictable.

In addition to the words which move, fetch and store single-cell items, the following words are valid for operations on one or more flag data residing on the data stack:

`AND OR XOR INVERT`

### A.3.1.3.2 Integers

A single-cell datum may be treated by a Standard Program as a signed integer. Moving and storing such data is performed as for any single-cell data. In addition to the universally-applicable operators for single-cell data specified above, the following mathematical and comparison operators are valid for single-cell signed integers:

**\* \*/ \*/MOD /MOD MOD + +! - / 1+ 1- ABS MAX MIN NEGATE 0< 0> < >**

Given the same number of bits, unsigned integers usually represent twice the number of absolute values representable by signed integers.

A single-cell datum may be treated by a Standard Program as an unsigned integer. Moving and storing such data is performed as for any single-cell data. In addition, the following mathematical and comparison operators are valid for single-cell unsigned integers:

**UM\* UM/MOD + +! - 1+ 1- \* U< U>**

### A.3.1.3.3 Addresses

An address is uniquely represented as a single cell unsigned number and can be treated as such when being moved to, from, or upon the stack. Conversely, each unsigned number represents a unique address (which is not necessarily an address of accessible memory). This one-to-one relationship between addresses and unsigned numbers forces an equivalence between address arithmetic and the corresponding operations on unsigned numbers.

Several operators are provided specifically for address arithmetic:

**CHAR+ CHARS CELL+ CELLS**

and, if the floating-point word set is present:

**FLOAT+ FLOATS SFLOAT+ SFLOATS DFLOAT+ DFLOATS**

A Standard Program may never assume a particular correspondence between a Forth address and the physical address to which it is mapped.

### A.3.1.3.4 Counted strings

Forth 94 moved toward the consistent use of the “*c-addr u*” representation of strings on the stack. The use of the alternate “address of counted string” stack representation is discouraged. The traditional Forth words **WORD** and **FIND** continue to use the “address of counted string” representation for historical reasons. The new word **C"**, added as a porting aid for existing programs, also uses the counted string representation.

Counted strings remain useful as a way to store strings in memory. This use is not discouraged, but when references to such strings appear on the stack, it is preferable to use the “*c-addr u*” representation.

### A.3.1.3.5 Execution tokens

The association between an execution token and a definition is static. Once made, it does not change with changes in the search order or anything else. However it may not be unique, e.g., the phrases

```
' 1+ and
' CHAR+
```

might return the same value.

#### A.3.1.3.6 Error results

The term *ior* was originally defined to describe the result of an input/output operation. This was extended to include other operations.

#### A.3.1.4 Cell-pair types

##### a) Storage and retrieval

Two operators are provided to fetch and store cell pairs:

```
2@ 2!
```

##### b) Manipulation on the stack

Additionally, these operators may be used to move cell pairs from, to and upon the stack:

```
2>R 2DROP 2DUP 2OVER 2R> 2SWAP 2ROT
```

##### c) Comparison

The following comparison operations are universally valid for cell pairs:

```
D= D0=
```

#### A.3.1.4.1 Double-Cell Integers

If a double-cell integer is to be treated as signed, the following comparison and mathematical operations are valid:

```
D+ D- D< D0< DABS DMAX DMIN DNEGATE M*/ M+
```

If a double-cell integer is to be treated as unsigned, the following comparison and mathematical operations are valid:

```
D+ D- UM/MOD DU<
```

#### A.3.1.4.2 Character strings

See: [A.3.1.3.4 Counted strings](#).

### A.3.2 The Implementation environment

#### A.3.2.1 Numbers

Traditionally, Forth has been implemented on two's-complement machines where there is a one-to-one mapping of signed numbers to unsigned numbers — any single cell item can be viewed either as a signed or unsigned number. Indeed, the signed representation of any positive number is identical to the equivalent

unsigned representation. Further, addresses are treated as unsigned numbers: there is no distinct pointer type. Arithmetic ordering on two's complement machines allows  $+$  and  $-$  to work on both signed and unsigned numbers. This arithmetic behavior is deeply embedded in common Forth practice.

x:2-complement

As a consequence of these behaviors, the likely range of signed numbers is  $-n - 1$  to  $n$  and for unsigned numbers is  $0$  to  $2n + 1$ . Where, where  $n$  is the largest positive signed number. Signed numbers in the  $0$  to  $n$  range are bitwise identical to the corresponding unsigned number.

There is no requirement to implement circular unsigned arithmetic, nor to set the range of unsigned numbers to the full size of a cell. There is historical precedent for limiting the range of  $u$  to that of  $+n$ , which is permissible when the cell size is greater than 16 bits.

#### A.3.2.1.2 Digit conversion

For example, an implementation might convert the characters “a” through “z” identically to the characters “A” through “Z”, or it might treat the characters “[ ” through “~” as additional digits with decimal values 36 through 71, respectively.

#### A.3.2.2 Arithmetic

##### A.3.2.2.1 Integer division

The Forth-79 Standard specifies that the signed division operators ( $/$ ,  $/\text{MOD}$ ,  $\text{MOD}$ ,  $\star/\text{MOD}$ , and  $\star/$ ) round non-integer quotients towards zero (symmetric division). Forth 83 changed the semantics of these operators to round towards negative infinity (floored division). Some in the Forth community have declined to convert systems and applications from the Forth-79 to the Forth-83 divide. To resolve this issue, a Forth-2012 system is permitted to supply either floored or symmetric operators. In addition, a standard system must provide a floored division primitive ( $\text{FM}/\text{MOD}$ ), a symmetric division primitive ( $\text{SM}/\text{REM}$ ), and a mixed precision multiplication operator ( $\text{M}\star$ ).

This compromise protects the investment made in current Forth applications; Forth-79 and Forth-83 programs are automatically compliant with Forth 94 with respect to division. In practice, the rounding direction rarely matters to applications. However, if a program requires a specific rounding direction, it can use the floored division primitive  $\text{FM}/\text{MOD}$  or the symmetric division primitive  $\text{SM}/\text{REM}$  to construct a division operator of the desired flavor. This simple technique can be used to convert Forth-79 and Forth-83 programs to Forth 94 without any analysis of the original programs.

##### ~~A.3.2.2.2 Other integer operations~~

~~Whether underflow occurs depends on the data type of the result. For example, the phrase  $1 - 2$  underflows and produces the largest unsigned number if the result is unsigned and produces the valid signed result  $-1$ .~~

#### A.3.2.3 Stacks

The only data type in Forth which has concrete rather than abstract existence is the stack entry. Even this primitive typing Forth only enforces by the hard reality of stack underflow or overflow. The programmer must have a clear idea of the number of stack entries to be consumed by the execution of a word and the number of entries that will be pushed back to a stack by the execution of a word. The observation of

anomalous occurrences on the data stack is the first line of defense whereby the programmer may recognize errors in an application program. It is also worth remembering that multiple stack errors caused by erroneous application code are frequently of equal and opposite magnitude, causing complementary (and deceptive) results.

For these reasons and a host of other reasons, the one unambiguous, uncontroversial, and indispensable programming discipline observed since the earliest days of Forth is that of providing a stack diagram for all additions to the application dictionary with the exception of static constructs such as **VARIABLE**s and **CONSTANT**s.

**A.3.2.3.2 Control-flow stack** The simplest use of control-flow words is to implement the basic control structures shown in figure [A.1](#).

Figure A.1: The basic control-flow patterns

In control flow every branch, or transfer of control, must terminate at some destination. A natural implementation uses a stack to remember the origin of forward branches and the destination of backward branches. At a minimum, only the location of each origin or destination must be indicated, although other implementation-dependent information also may be maintained.

An origin is the location of the branch itself. A destination is where control would continue if the branch were taken. A destination is needed to resolve the branch address for each origin, and conversely, if every control-flow path is completed no unused destinations can remain.

With the addition of just three words (**AHEAD**, **CS-ROLL** and **CS-PICK**), the basic control-flow words supply the primitives necessary to compile a variety of transportable control structures. The abilities required are compilation of forward and backward conditional and unconditional branches and compile-time management of branch origins and destinations. Table [A.1](#) shows the desired behavior.

The requirement that control-flow words are properly balanced by other control-flow words makes reasonable the description of a compile-time implementation-defined *control-flow stack*. There is no prescription as to how the control-flow stack is implemented, e.g., data stack, linked list, special array. Each element of the control-flow stack mentioned above is the same size.

With these tools, the remaining basic control-structure elements, shown in figure [A.2](#), can be defined. The stack notation used here for immediate words is ( *compilation / execution* ).

```
: WHILE ( dest -- orig dest / flag -- )
```

Table A.1: Compilation behavior of control-flow words

at compile-time, word:	supplies:	resolves:	is used to:
<b>IF</b>	<i>orig</i>		mark origin of forward conditional branch
<b>THEN</b>		<i>orig</i>	resolve <b>IF</b> or <b>AHEAD</b>
<b>BEGIN</b>	<i>dest</i>		mark backward destination
<b>AGAIN</b>		<i>dest</i>	resolve with backward unconditional branch
<b>UNTIL</b>		<i>dest</i>	resolve with backward conditional branch
<b>AHEAD</b>	<i>orig</i>		mark origin of forward unconditional branch
<b>CS-PICK</b>			copy item on control-flow stack
<b>CS-ROLL</b>			reorder items on control-flow stack

```

\ conditional exit from loops
POSTPONE IF      \ conditional forward brach
1 CS-ROLL       \ keep dest on top
; IMMEDIATE

: REPEAT ( orig dest -- / -- )
\ resolve a single WHILE and return to BEGIN
POSTPONE AGAIN  \ uncond. backward branch to dest
POSTPONE THEN  \ resolve forward branch from orig
; IMMEDIATE

: ELSE ( orig1 -- orig2 / -- )
\ resolve IF supplying alternate execution
POSTPONE AHEAD  \ unconditional forward branch orig2
1 CS-ROLL       \ put orig1 back on top
POSTPONE THEN  \ resolve forward branch from orig1
; IMMEDIATE

```

Forth control flow provides a solution for well-known problems with strictly structured programming.

The basic control structures can be supplemented, as shown in the examples in figure A.3, with additional **WHILE**s in **BEGIN ... UNTIL** and **BEGIN ... WHILE ... REPEAT** structures. However, for each additional **WHILE** there must be a **THEN** at the end of the structure. **THEN** completes the syntax with **WHILE** and indicates where to continue execution when the **WHILE** transfers control. The use of more than one additional **WHILE** is possible but not common. Note that if the user finds this use of **THEN** undesirable, an alias with a more likable name could be defined.

Additional actions may be performed between the control flow word (the **REPEAT** or **UNTIL**) and the **THEN** that matches the additional **WHILE**. Further, if additional actions are desired for normal termination and early termination, the alternative actions may be separated by the ordinary Forth **ELSE**. The termination actions are all specified after the body of the loop.

Note that **REPEAT** creates an anomaly when matching the **WHILE** with **ELSE** or **THEN**, most notably when compared with the **BEGIN...UNTIL** case. That is, there will be one less **ELSE** or **THEN** than there are

Figure A.2: Additional basic control-flow patterns

WHILEs because **REPEAT** resolves one **THEN**. As above, if the user finds this count mismatch undesirable, **REPEAT** could be replaced in-line by its own definition.

Other loop-exit control-flow words, and even other loops, can be defined. The only requirements are that the control-flow stack is properly maintained and manipulated.

The simple implementation of the **CASE** structure below is an example of control structure extension. Note the maintenance of the data stack to prevent interference with the possible control-flow stack usage.

```

0 CONSTANT CASE IMMEDIATE ( init count of OFs )

: OF ( #of -- orig #of+1 / x -- )
  1+ ( count OFs )
  >R ( move off the stack in case the control-flow )
    ( stack is the data stack. )
  POSTPONE OVER POSTPONE = ( copy and test case value)
  POSTPONE IF ( add orig to control flow stack )
  POSTPONE DROP ( discards case value if = )
  R> ( we can bring count back now )
; IMMEDIATE

: ENDOF ( orig1 #of -- orig2 #of )
  >R ( move off the stack in case the control-flow )
    ( stack is the data stack. )
  POSTPONE ELSE
  R> ( we can bring count back now )
; IMMEDIATE

: ENDCASE ( orig1..orign #of -- )

```

Figure A.3: Extended control-flow patterns

```

POSTPONE DROP      ( discard case value )
0 ?DO
  POSTPONE THEN
LOOP
; IMMEDIATE

```

### A.3.2.3.3 Return stack

The restrictions in section [3.2.3.3 Return stack](#) are necessary if implementations are to be allowed to place loop parameters on the return stack.

### A.3.2.6 Environmental queries

The size in address units of various data types may be determined by phrases such as `1 CHARS`. Similarly, alignment may be determined by phrases such as `1 ALIGNED`.

The environmental queries are divided into two groups: those that always produce the same value and those that might not. The former groups include entries such as `MAX-N`. This information is fixed by the hardware or by the design of the Forth system; a user is guaranteed that asking the question once is sufficient.

The other, now obsolescent, group of queries are for things that may legitimately change over time. For

example an application might test for the presence of the Double Number word set using an environment query. If it is missing, the system could invoke a system-dependent process to load the word set. The system is permitted to change **ENVIRONMENT?**'s database so that subsequent queries about it indicate that it is present.

Note that a query that returns an “unknown” response could produce a “known” result on a subsequent query.

#### **A.3.2.7 Obsolescent Environmental Queries**

When reviewing the Forth 94 Standard, the question of adapting the word set queries had to be addressed. Despite the recommendation in Forth 94, word set queries have not been supported in a meaningful way by many systems. Consequently, these queries are not used by many programmers. The committee was unwilling to exacerbate the problem by introducing additional queries for the revised word sets. The committee has therefore declared the word set environment queries (see table 3.6) as obsolescent with the intention of removing them altogether in the next revision. They are retained in this standard to support existing Forth 94 programs. New programs should not use them.

#### **A.3.2.8 Extension queries**

### **A.3.3 The Forth dictionary**

A Standard Program may redefine a standard word with a non-standard definition. The program is still standard (since it can be built on any Standard System), but the effect is to make the combined entity (Standard System plus Standard Program) a non-standard system.

#### **A.3.3.1 Name space**

##### **A.3.3.1.2 Definition names**

The language in this section is there to ensure the portability of Standard Programs. If a program uses something outside the Standard that it does not provide itself, there is no guarantee that another implementation will have what the program needs to run. There is no intent whatsoever to imply that all Forth programs will be somehow lacking or inferior because they are not standard; some of the finest jewels of the programmer's art will be non-standard. At the same time, the committee is trying to ensure that a program labeled “Standard” will meet certain expectations, particularly with regard to portability.

In many system environments the input source is unable to supply certain non-graphic characters due to external factors, such as the use of those characters for flow control or editing. In addition, when interpreting from a text file, the parsing function specifically treats non-graphic characters like spaces; thus words received by the text interpreter will not contain embedded non-graphic characters. To allow implementations in such environments to call themselves standard, this minor restriction on Standard Programs is necessary.

A Standard System is allowed to permit the creation of definition names containing non-graphic characters. Historically, such names were used for keyboard editing functions and “invisible” words.

#### **A.3.3.2 Code space**

#### **A.3.3.3 Data space**

The words **>IN**, **BASE**, **BLK**, **SCR**, **SOURCE**, **SOURCE-ID**, **STATE** contain information used by the Forth system in its operation and may be of use to the application. Any assumption made by the application

about data available in the Forth system it did not store other than the data just listed is an environmental dependency.

There is no point in specifying (in the Standard) both what is and what is not addressable. A Standard Program may NOT address:

- Directly into the data or return stacks;
- Into a definition's data field if not stored by the application.

The read-only restrictions arise because some Forth systems run from ROM and some share I/O buffers with other users or systems. Portable programs cannot know which areas are affected, hence the general restrictions.

#### A.3.3.3.1 Address alignment

Some processors have restrictions on the addresses that can be used by memory access instructions. For example, some architectures require 16-bit data to be loaded or stored only at even addresses and 32-bit data only at addresses that are multiples of four.

An implementor can handle these alignment restrictions in one of two ways. Forth's memory access words (`@`, `!`, `+`, etc.) could be implemented in terms of smaller-width access instructions, which have no alignment restrictions. For example, on a system with 16-bit cells, `@` could be implemented with two byte-fetch instructions and a reassembly of the bytes into a 16-bit cell. Although this conceals hardware restrictions from the programmer, it is inefficient, and may have unintended side effects in some hardware environments. An alternate implementation could define each memory-access word using the native instructions that most closely match the word's function. The 16-bit cell system could implement `@` using the processor's 16-bit fetch instruction, in this case, the responsibility for giving `@` a correctly-aligned address falls on the programmer. A portable program must assume that alignment may be required and follow the requirements of this section.

#### A.3.3.3.2 Contiguous regions

The data space of a Forth system comes in discontinuous regions. The location of some regions is provided by the system, some by the program. Data space is contiguous within regions, allowing address arithmetic to generate valid addresses only within a single region. A Standard Program cannot make any assumptions about the relative placement of multiple regions in memory.

Section 3.3.3.2 does prescribe conditions under which contiguous regions of data space may be obtained. For example:

```
CREATE TABLE 1 C, 2 C, ALIGN 1000 , 2000 ,
```

makes a table whose address is returned by `TABLE`. In accessing this table,

<code>TABLE C@</code>	will return 1
<code>TABLE CHAR+ C@</code>	will return 2
<code>TABLE 2 CHARS + ALIGNED @</code>	will return 1000
<code>TABLE 2 CHARS + ALIGNED CELL+ @</code>	will return 2000.

Similarly,

```
CREATE DATA 1000 ALLOT
```

makes an array 1000 address units in size. A more portable strategy would define the array in application units, such as:

```
500 CONSTANT NCELLS
CREATE CELL-DATA NCELLS CELLS ALLOT
```

This array can be indexed like this:

```
: LOOK NCELLS 0 DO CELL-DATA I CELLS + ? LOOP ;
```

#### A.3.3.3.6 Other transient regions

In many existing Forth systems, these areas are at [HERE](#) or just beyond it, hence the many restrictions.

$(2 * n) + 2$  is the size of a character string containing the unpunctuated binary representation of the maximum double number with a leading minus sign and a trailing space.

Implementation note: Since the minimum value of  $n$  is 16, the absolute minimum size of the pictured numeric output string is 34 characters. But if your implementation has a larger  $n$ , you must also increase the size of the pictured numeric output string.

### A.3.4 The Forth text interpreter

#### A.3.4.3 Semantics

The “initiation semantics” correspond to the code that is executed upon entering a definition, analogous to the code executed by **EXIT** upon leaving a definition. The “run-time semantics” correspond to code fragments, such as literals or branches, that are compiled inside colon definitions by words with explicit compilation semantics.

In a Forth cross compiler, the execution semantics may be specified to occur in the host system only, the target system only, or in both systems. For example, it may be appropriate for words such as **CELLS** to execute on the host system returning a value describing the target, for colon definitions to execute only on the target, and for **CONSTANT** and **VARIABLE** to have execution behaviors on both systems. Details of cross compiler behavior are beyond the scope of this standard.

#### A.3.4.3.2 Interpretation semantics

For a variety of reasons, this standard does not define interpretation semantics for every word. Examples of these words are **>R**, **.**, **DO**, and **IF**. Nothing in this Standard precludes an implementation from providing interpretation semantics for these words, such as interactive control-flow words. However, a Standard Program may not use them in interpretation state.

### A.3.4.5 Compilation

Compiler recursion at the definition level consumes excessive resources, especially to support locals. The committee does not believe that the benefits justify the costs. Nesting definitions is also not common practice and won't work on many systems.

## A.4 Documentation requirements

### A.4.1 System documentation

### A.4.2 Program documentation

## A.5 Compliance and labeling

### A.5.1 Forth-2012 systems

Section 5.1 defines the criteria that a system must meet in order to justify the label "Forth-2012 System". Briefly, the minimum requirement is that the system must "implement" the Core word set. There are several ways in which this requirement may be met. The most obvious is that all Core words may be in a pre-compiled kernel. This is not the only way of satisfying the requirement, however. For example, some words may be provided in source blocks or files with instructions explaining how to add them to the system if they are needed. So long as the words are provided in such a way that the user can obtain access to them with a clear and straightforward procedure, they may be considered to be present.

A Forth cross compiler has many characteristics in common with a standard system, in that both use similar compiling tools to process a program. However, in order to fully specify a Forth-2012 standard cross compiler it would be necessary to address complex issues dealing with compilation and execution semantics in both host and target environments as well as ROMability issues. The level of effort to do this properly has proved to be impractical at this time. As a result, although it may be possible for a Forth cross compiler to correctly prepare a Forth-2012 standard program for execution in a target environment, it is inappropriate for a cross compiler to be labeled a Forth-2012 standard system.

### A.5.2 Forth-2012 programs

#### A.5.2.2 Program labeling

Declaring an environmental dependency should not be considered undesirable, merely an acknowledgment that the author has taken advantage of some assumed architecture. For example, by acknowledging an environmental dependency on big-endian memory access, a programmer becomes ~~entitled~~ entitled to use the ~~lower~~ lowest memory address of a cell as its the most significant byte.

Because all programs require space for data and instructions, and time to execute those instructions, they depend on the presence of an environment providing those resources. It is impossible to predict how little of some of these resources (e.g. stack space) might be necessary to perform some task, so this standard does not do so.

On the other hand, as a program requires increasing levels of resources, there will probably be successively fewer systems on which it will execute successfully. An algorithm requiring an array of  $10^9$  cells might run on fewer computers than one requiring only  $10^3$ .

Since there is also no way of knowing what minimum level of resources will be implemented in a system useful for at least some tasks, any program performing real work labeled simply a “Standard Forth-2012 Program” is unlikely to be labeled correctly.

## A.6 Glossary

In this and following sections we present rationales for the handling of specific words: why we included them, why we placed them in certain word sets, or why we specified their names or meaning as we did.

Words in this section are organized by word set, retaining their index numbers for easy cross-referencing to the glossary.

Historically, many Forth systems have been written in Forth. Many of the words in Forth originally had as their primary purpose support of the Forth system itself. For example, **WORD** and **FIND** are often used as the principle instruments of the Forth text interpreter, and **CREATE** in many systems is the primitive for building dictionary entries. In defining words such as these in a standard way, we have endeavored not to do so in such a way as to preclude their use by implementors. One of the features of Forth that has endeared it to its users is that the same tools that are used to implement the system are available to the application programmer — a result of this approach is the compactness and efficiency that characterizes most Forth implementations.

### A.6.1.0070 `'`

Typical use: ... `' name`.

Many Forth systems use a state-smart tick. Many do not. Forth-2012 follows the usage of Forth 94.

See: [A.3.4.3.2 Interpretation semantics](#), [A.6.1.1550 FIND](#).

### A.6.1.0080 `(`

Typical use: ... `( ccc ) ...`

### A.6.1.0140 `+LOOP`

Typical use: `: X ... limit first DO ... step +LOOP ;`

### A.6.1.0150 `,`

The use of `,` (comma) for compiling execution tokens is not portable.

See: [6.2.0945 COMPILER](#), `,`

### A.6.1.0190 `."`

Typical use: `: X ... ." ccc" ... ;`

An implementation may define interpretation semantics for `."` if desired. In one plausible implementation, interpreting `."` would display the delimited message. In another plausible implementation, interpreting `."` would compile code to display the message later. In still another plausible implementation, interpreting `."` would be treated as an exception. Given this variation a Standard Program may not use `."` while interpreting. Similarly, a Standard Program may not compile [POSTPONE](#) `."` inside a new word, and then use that word while interpreting.

**A.6.1.0450** :

Typical use: `: name ... ;`

In Forth 83, this word was specified to alter the search order. This specification is explicitly removed in this standard. We believe that in most cases this has no effect; however, systems that allow many search orders found the Forth-83 behavior of colon very undesirable.

Note that colon does not itself invoke the compiler. Colon sets compilation state so that later words in the parse area are compiled.

**A.6.1.0460** ;

Typical use: `: name ... ;`

One function performed by both `; and ;CODE` is to allow the current definition to be found in the dictionary. If the current definition was created by `:NONAME` the current definition has no definition name and thus cannot be found in the dictionary. If `:NONAME` is implemented the Forth compiler must maintain enough information about the current definition to allow `; and ;CODE` to determine whether or not any action must be taken to allow it to be found.

**A.6.1.0550** >BODY

*a-addr* is the address that `HERE` would have returned had it been executed immediately after the execution of the `CREATE` that defined *xt*.

**A.6.1.0680** ABORT"

Typical use: `: X ... test ABORT" ccc" ... ;`

**A.6.1.0695** ACCEPT

Specification of a non-zero, positive integer count ( $+n_1$ ) for `ACCEPT` allows some implementors to continue their practice of using a zero or negative value as a flag to trigger special behavior. Insofar as such behavior is outside the standard, Standard Programs cannot depend upon it, but the committee doesn't wish to preclude it unnecessarily. Because actual values are almost always small integers, no functionality is impaired by this restriction.

It is recommended that all non-graphic characters be reserved for editing or control functions and not be stored in the input string.

Because external system hardware and software may perform the `ACCEPT` function, when a line terminator is received the action of the cursor, and therefore the display, is implementation-defined. It is recommended that the cursor remain immediately following the entered text after a line terminator is received.

**A.6.1.0705** ALIGN

In this standard we have attempted to provide transportability across various CPU architectures. One of the frequent causes of transportability problems is the requirement of cell-aligned addresses on some CPUs. On these systems, `ALIGN` and `ALIGNED` may be required to build and traverse data structures built with `C,`. Implementors may define these words as no-ops on systems for which they aren't functional.

**A.6.1.0760 BEGIN**

Typical use:

```
: X ... BEGIN ... test UNTIL ;
```

or

```
: X ... BEGIN ... test WHILE ... REPEAT ;
```

**A.6.1.0770 BL**

Because space is used throughout Forth as the standard delimiter, this word is the only way a program has to find and use the system value of “space”. The value of a space character can not be obtained with **CHAR**, for instance.

**A.6.1.0880 CELL+**

As with **ALIGN** and **ALIGNED**, the words **CELLS** and **CELL+** were added to aid in transportability across systems with different cell sizes. They are intended to be used in manipulating indexes and addresses in integral numbers of cell-widths. Example:

```
2VARIABLE DATA
0 100 DATA 2!
DATA @ . 100
DATA CELL+ @ . 0
```

**A.6.1.0890 CELLS**

Example:

```
CREATE NUMBERS 100 CELLS ALLOT
```

Allots space in the array NUMBERS for 100 cells of data.

**A.6.1.0895 CHAR**

Typical use: ... **CHAR** A **CONSTANT** "A" ...

**A.6.1.0950 CONSTANT**

Typical use: ... **DECIMAL** 10 **CONSTANT** TEN ...

**A.6.1.1000 CREATE**

The data-field address of a word defined by **CREATE** is given by the data-space pointer immediately following the execution of **CREATE**.

Reservation of data field space is typically done with **ALLOT**.

Typical use: ... **CREATE** SOMETHING ...

**A.6.1.1240 DO**

Typical use:

```
: X ... limit first DO ... LOOP ;
```

or

`: X ... limit first DO ... step +LOOP ;`

#### A.6.1.1250 **DOES>**

Typical use: `: X ... DOES> ... ;`

Following **DOES>**, a Standard Program may not make any assumptions regarding the ability to find either the name of the definition containing the **DOES>** or any previous definition whose name may be concealed by it. **DOES>** effectively ends one definition and begins another as far as local variables and control-flow structures are concerned. The compilation behavior makes it clear that the user is not entitled to place **DOES>** inside any control-flow structures.

#### A.6.1.1310 **ELSE**

Typical use: `: X ... test IF ... ELSE ... THEN ;`

#### A.6.1.1345 **ENVIRONMENT?**

In a Standard System that contains only the Core word set, effective use of **ENVIRONMENT?** requires either its use within a definition, or the use of user-supplied auxiliary definitions. The Core word set lacks both a direct method for collecting a string in interpretation state (**11.6.1.2165 S** is in an optional word set) and also a means to test the returned flag in interpretation state (e.g. the optional **15.6.2.2532 [IF]**).

#### A.6.1.1380 **EXIT**

Typical use: `: X ... test IF ... EXIT THEN ... ;`

#### A.6.1.1550 **FIND**

One of the more difficult issues which the committee took on was the problem of divorcing the specification of implementation mechanisms from the specification of the Forth language. Three basic implementation approaches can be quickly enumerated:

- 1) Threaded code mechanisms. These are the traditional approaches to implementing Forth, but other techniques may be used.
- 2) Subroutine threading with “macro-expansion” (code copying). Short routines, like the code for **DUP**, are copied into a definition rather than compiling a JSR reference.
- 3) Native coding with optimization. This may include stack optimization (replacing such phrases as **SWAP ROT +** with one or two machine instructions, for example), parallelization (the trend in the newer RISC chips is to have several functional subunits which can execute in parallel), and so on.

The initial requirement (inherited from Forth 83) that compilation addresses be compiled into the dictionary disallowed type 2 and type 3 implementations.

Type 3 mechanisms and optimizations of type 2 implementations were hampered by the explicit specification of immediacy or non-immediacy of all standard words. **POSTPONE** allowed de-specification of immediacy or non-immediacy for all but a few Forth words whose behavior must be **STATE**-independent.

One type 3 implementation, Charles Moore’s cmForth, has both compiling and interpreting versions of many Forth words. At the present, this appears to be a common approach for type 3 implementations. The committee felt that this implementation approach must be allowed. Consequently, it is

possible that words without interpretation semantics can be found only during compilation, and other words may exist in two versions: a compiling version and an interpreting version. Hence the values returned by **FIND** may depend on **STATE**, and **'** and **[ ' ]** may be unable to find words without interpretation semantics.

#### A.6.1.1561 **FM/MOD**

By introducing the requirement for “floored” division, Forth 83 produced much controversy and concern on the part of those who preferred the more common practice followed in other languages of implementing division according to the behavior of the host CPU, which is most often symmetric (rounded toward zero). In attempting to find a compromise position, this standard provides primitives for both common varieties, floored and symmetric (see **SM/REM**). **FM/MOD** is the floored version.

The committee considered providing two complete sets of explicitly named division operators, and declined to do so on the grounds that this would unduly enlarge and complicate the standard. Instead, implementors may define the normal division words in terms of either **FM/MOD** or **SM/REM** providing they document their choice. People wishing to have explicitly named sets of operators are encouraged to do so. **FM/MOD** may be used, for example, to define:

```

: /_MOD ( n1 n2 -- n3 n4 ) >R S>D R> FM/MOD ;
: /_ ( n1 n2 -- n3 ) /_MOD SWAP DROP ;
: _MOD ( n1 n2 -- n3 ) /_MOD DROP ;
: */_MOD ( n1 n2 n3 -- n4 n5 ) >R M* R> FM/MOD ;
: */_ ( n1 n2 n3 -- n4 ) */_MOD SWAP DROP ;

```

#### A.6.1.1700 **IF**

Typical use:

```
: X ... test IF ... THEN ... ;
```

or

```
: X ... test IF ... ELSE ... THEN ... ;
```

#### A.6.1.1710 **IMMEDIATE**

Typical use: `: X ... ; IMMEDIATE`

#### A.6.1.1720 **INVERT**

The word **NOT** was originally provided in Forth as a flag operator to make control structures readable. Under its intended usage the following two definitions would produce identical results:

```

: ONE ( flag -- )
  IF ." true" ELSE ." false" THEN ;
: TWO ( flag -- )
  NOT IF ." false" ELSE ." true" THEN ;

```

This was common usage prior to the Forth-83 Standard which redefined **NOT** as a cell-wide one’s-complement operation, functionally equivalent to the phrase `-1 XOR`. At the same time, the data type manipulated by this word was changed from a flag to a cell-wide collection of bits and the standard

value for true was changed from “1” (rightmost bit only set) to “-1” (all bits set). As these definitions of **TRUE** and **NOT** were incompatible with their previous definitions, many Forth users continue to rely on the old definitions. Hence both versions are in common use.

Therefore, usage of **NOT** cannot be standardized at this time. The two traditional meanings of **NOT** — that of negating the sense of a flag and that of doing a one’s complement operation — are made available by **0=** and **INVERT**, respectively.

#### A.6.1.1730 **J**

**J** may only be used with a nested **DO ... LOOP**, **DO ... +LOOP**, **?DO ... LOOP**, or **?DO ... +LOOP**, for example, in the form:

```
: X ... DO ... DO ... J ... LOOP ... +LOOP ... ;
```

#### A.6.1.1750 **KEY**

Use of **KEY** indicates that the application is processing primitive characters. Some input devices, e.g., keyboards, may provide more information than can be represented as a primitive character and such an event may be received as an implementation-specific sequence of primitive characters.

See [A.10.6.2.1305 EKEY](#).

#### A.6.1.1760 **LEAVE**

Note that **LEAVE** immediately exits the loop. No words following **LEAVE** within the loop will be executed. Typical use:

```
: X ... DO ... IF ... LEAVE THEN ... LOOP ... ;
```

#### A.6.1.1780 **LITERAL**

Typical use: `: X ... [ x ] LITERAL ... ;`

#### A.6.1.1800 **LOOP**

Typical use:

```
: X ... limit first DO ... LOOP ... ;
```

or

```
: X ... limit first ?DO ... LOOP ... ;
```

#### A.6.1.1810 **M\***

This word is a useful early step in calculation, going to extra precision conveniently. It has been in use since the Forth systems of the early 1970’s.

#### A.6.1.1900 **MOVE**

**CMOVE** and **CMOVE>** are the primary move operators in Forth 83. They specify a behavior for moving that implies propagation if the move is suitably invoked. In some hardware, this specific behavior cannot be achieved using the best move instruction. Further, **CMOVE** and **CMOVE>** move characters; Forth needs a move instruction capable of dealing with address units. Thus **MOVE** has been defined and added to the Core word set, and **CMOVE** and **CMOVE>** have been moved to the String word set.

**A.6.1.2033 POSTPONE**

Typical use:

```
: ENDF POSTPONE THEN ; IMMEDIATE
: X ... IF ... ENDF ... ;
```

**POSTPONE** replaces most of the functionality of **COMPILE** and **[COMPILE]**. **COMPILE** and **[COMPILE]** are used for the same purpose: postpone the compilation behavior of the next word in the parse area. **COMPILE** was designed to be applied to non-immediate words and **[COMPILE]** to immediate words. This burdens the programmer with needing to know which words in a system are immediate. Consequently, Forth standards have had to specify the immediacy or non-immediacy of all words covered by the standard. This unnecessarily constrains implementors.

A second problem with **COMPILE** is that some programmers have come to expect and exploit a particular implementation, namely:

```
: COMPILE R> DUP @ , CELL+ >R ;
```

This implementation will not work on native code Forth systems. In a native code Forth using inline code expansion and peephole optimization, the size of the object code produced varies; this information is difficult to communicate to a “dumb” **COMPILE**. A “smart” (i.e., immediate) **COMPILE** would not have this problem, but this was forbidden in previous standards.

For these reasons, **COMPILE** has not been included in the standard and **[COMPILE]** has been moved in favor of **POSTPONE**. Additional discussion can be found in Hayes, J.R., “Postpone”, *Proceedings of the 1989 Rochester Forth Conference*.

**A.6.1.2120 RECURSE**

Typical use: `: X ... RECURSE ... ;`

This is Forth’s recursion operator; in some implementations it is called **MYSELF**. The usual example is the coding of the factorial function.

```
: FACTORIAL ( +n1 -- +n2)
  DUP 2 < IF DROP 1 EXIT THEN
  DUP 1- RECURSE *
;
```

$n_2 = n_1(n_1 - 1)(n_1 - 2) \cdots (2)(1)$ , the product of  $n_1$  with all positive integers less than itself (as a special case, zero factorial equals one). While beloved of computer scientists, recursion makes unusually heavy use of both stacks and should therefore be used with caution. See alternate definition in **A.6.1.2140 REPEAT**.

**A.6.1.2140 REPEAT**

Typical use:

```
: FACTORIAL ( +n1 -- +n2 )
  DUP 2 < IF DROP 1 EXIT THEN
  DUP
  BEGIN DUP 2 > WHILE
    1- SWAP OVER * SWAP
```

```

    REPEAT DROP
  ;

```

**A.6.1.2165 S"**

Typical use: `: X ... S" ccc" ... ;`

**A.6.1.2214 SM/REM**

See the previous discussion of division under **FM/MOD**. **SM/REM** is the symmetric-division primitive, which allows programs to define the following symmetric-division operators:

```

: /-REM ( n1 n2 -- n3 n4 ) >R S>D R> SM/REM ;
: /- ( n1 n2 -- n3 ) /-REM SWAP DROP ;
: -REM ( n1 n2 -- n3 ) /-REM DROP ;
: */-REM ( n1 n2 n3 -- n4 n5 ) >R M* R> SM/REM ;
: */- ( n1 n2 n3 -- n4 ) */-REM SWAP DROP ;

```

**A.6.1.2216 SOURCE**

**SOURCE** simplifies the process of directly accessing the input buffer by hiding the differences between its location for different input sources. This also gives implementors more flexibility in their implementation of buffering mechanisms for different input sources. The committee moved away from an input buffer specification consisting of a collection of individual variables.

**A.6.1.2250 STATE**

Although **EVALUATE**, **LOAD**, **INCLUDE-FILE** and **INCLUDED** are not listed as words which alter **STATE**, the text interpreted by any one of these words could include one or more words which explicitly alter **STATE**. **EVALUATE**, **LOAD**, **INCLUDE-FILE** and **INCLUDED** do not in themselves alter **STATE**.

**STATE** does not nest with text interpreter nesting. For example, the code sequence:

```
: FOO S" ]" EVALUATE ; FOO
```

will leave the system in compilation state. Similarly, after **LOAD**ing a block containing **]**, the system will be in compilation state.

Note that **]** does not affect the parse area and that the only effect that **:** has on the parse area is to parse a word. This entitles a program to use these words to set the state with known side-effects on the parse area. For example:

```
: NOP : POSTPONE ; IMMEDIATE ;

NOP ALIGN
NOP ALIGNED
```

Some non-compliant systems have **]** invoke a compiler loop in addition to setting **STATE**. Such a system would inappropriately attempt to compile the second use of **NOP**.

**A.6.1.2270 THEN**

Typical use:

```
: X ... test IF ... THEN ... ;
```

or

```
: X ... test IF ... ELSE ... THEN ... ;
```

**A.6.1.2380 UNLOOP**

Typical use:

```
: X ...
  limit first DO
    ... test IF ... UNLOOP EXIT THEN ...
  LOOP ...
;
```

**UNLOOP** allows the use of **EXIT** within the context of **DO ... LOOP** and related do-loop constructs. **UNLOOP** as a function has been called UNDO. **UNLOOP** is more indicative of the action: nothing gets undone — we simply stop doing it.

**A.6.1.2390 UNTIL**

Typical use: `: X ... BEGIN ... test UNTIL ... ;`

**A.6.1.2410 VARIABLE**

Typical use: `VARIABLE XYZ`

**A.6.1.2430 WHILE**

Typical use: `: X ... BEGIN ... test WHILE ... REPEAT ... ;`

**A.6.1.2450 WORD**

Typical use: `char WORD ccc(char)`

**A.6.1.2500 [**

Typical use: `: X ... [ 4321 ] LITERAL ... ;`

**A.6.1.2510 [ ' ]**

Typical use: `: X ... [ ' ] name ... ;`

See: [A.6.1.1550 FIND](#).

**A.6.1.2520 [CHAR]**

Typical use: `: X ... [CHAR] c ... ;`

**A.6.1.2540 ]**

Typical use: `: X ... [ 4321 ] LITERAL ... ;`

## A.6.2 Core extension words

The words in this collection fall into several categories:

- Words that are in common use but are deemed less essential than Core words (e.g., **0<>**);
- Words that are in common use but can be trivially defined from Core words (e.g., **FALSE**);
- Words that are primarily useful in narrowly defined types of applications or are in less frequent use (e.g., **PARSE**);
- Words that are being deprecated in favor of new words introduced to solve specific problems.

Because of the varied justifications for inclusion of these words, the committee does not encourage implementors to offer the complete collection, but to select those words deemed most valuable to their clientele.

### A.6.2.0200 . (

Typical use: `. ( ccc)`

### A.6.2.0210 .R

In `.R`, “R” is short for RIGHT.

### A.6.2.0340 2>R

The primary advantage of `2>R` is that it puts the top stack entry on the top of the return stack. For instance, a double-cell number may be transferred to the return stack and still have the most significant cell accessible on the top of the return stack.

### A.6.2.0410 2R>

Note that `2R>` is not equivalent to `R> R>`. Instead, it mirrors the action of `2>R` (see A.6.2.0340).

### A.6.2.0455 :NONAME

Typical use:

```
DEFER print
:NONAME ( n -- ) . ; IS print
```

Note: `RECURSE` and `DOES>` are allowed within a `:NONAME` definition.

### A.6.2.0620 ?DO

Typical use:

```
: X ... ?DO ... LOOP ... ;
```

### A.6.2.0700 AGAIN

Typical use: `: X ... BEGIN ... AGAIN ... ;`

Unless word-sequence has a way to terminate, this is an endless loop.

### A.6.2.0825 BUFFER:

**BUFFER:** provides a means of defining an uninitialized buffer. In systems that use a single memory space, this can effectively be defined as:

```

: BUFFER: ( u "<name>" -- ; -- addr )
  CREATE ALLOT
;

```

However, many systems profit from a separation of uninitialized and initialized data areas. Such systems can implement **BUFFER:** so that it allocates memory from a separate uninitialized memory area. Embedded systems can take advantage of the lack of initialization of the memory area while hosted systems are permitted to **ALLOCATE** a buffer. A system may select a region of memory for performance reasons. A detailed knowledge of the memory allocation within the system is required to provide a version of **BUFFER:** that can take advantage of the system.

It should be noted that the memory buffer provided by **BUFFER:** is not initialized by the system and that if the application requires it to be initialized, it is the responsibility of the application to initialize it.

#### A.6.2.0855 **C"**

Typical use: `: X ... C" ccc" ... ;`

See: [A.3.1.3.4 Counted strings](#).

#### A.6.2.0873 **CASE**

Typical use:

```

: X ...
  CASE
    test1 OF ... ENDOF
    testn OF ... ENDOF
    ... ( default )
  ENDCASE ...
;

```

#### A.6.2.0945 **COMPILE,**

**COMPILE,** is the compilation equivalent of **EXECUTE**.

In traditional threaded-code implementations, compilation is performed by `,` (comma). This usage is not portable; it doesn't work for subroutine-threaded, native code, or relocatable implementations. Use of **COMPILE,** is portable.

In most systems it is possible to implement **COMPILE,** so it will generate code that is optimized to the same extent as code that is generated by the normal compilation process. However, in some implementations there are two different "tokens" corresponding to a particular definition name: the normal "execution token" that is used while interpreting or with **EXECUTE**, and another "compilation token" that is used while compiling. It is not always possible to obtain the compilation token from the execution token. In these implementations, **COMPILE,** might not generate code that is as efficient as normally compiled code.

The intention is that **COMPILE,** can be used as follows to write the classic interpreter/compiler loop:

```

...                               ( c-addr )
FIND ?DUP IF                     ( xt +-1 )
  STATE @ IF                       ( xt +-1 )

```

```

    0> IF EXECUTE ELSE COMPILE, THEN ( ??? )
    ELSE                               ( xt +-1 )
      DROP EXECUTE                     ( ??? )
    THEN
    ELSE                               ( c-addr )
      ( whatever you do for an undefined word )
    THEN
    . . .

```

Thus the interpretation semantics are left undefined, as **COMPILE**, will not be executed during interpretation.

#### A.6.2.1342 **ENDCASE**

Typical use:

```

: X ...
  CASE
    test1 OF ... ENDOF
    testn OF ... ENDOF
    ... ( default )
  ENDCASE ...
;

```

#### A.6.2.1343 **ENDOF**

Typical use:

```

: X ...
  CASE
    test1 OF ... ENDOF
    testn OF ... ENDOF
    ... ( default )
  ENDCASE ...
;

```

#### A.6.2.1850 **MARKER**

As dictionary implementations have become more elaborate and in some cases have used multiple address spaces, **FORGET** has become prohibitively difficult or impossible to implement on many Forth systems. **MARKER** greatly eases the problem by making it possible for the system to remember “landmark information” in advance that specifically marks the spots where the dictionary may at some future time have to be rearranged.

#### A.6.2.1950 **OF**

Typical use:

```

: X ...
  CASE
    test1 OF ... ENDOF
    testn OF ... ENDOF
    ... ( default )

```

```

    ENDCASE ...
;

```

#### A.6.2.2000 **PAD**

**PAD** has been available as scratch storage for strings since the earliest Forth implementations. It was brought to our attention that many programmers are reluctant to use **PAD**, fearing incompatibilities with system uses. **PAD** is specifically intended as a programmer convenience, however, which is why we documented the fact that no standard words use it.

#### A.6.2.2008 **PARSE**

Typical use: *char* **PARSE** *ccc*(*char*)

The traditional Forth word for parsing is **WORD**. **PARSE** solves the following problems with **WORD**:

- a) **WORD** always skips leading delimiters. This behavior is appropriate for use by the text interpreter, which looks for sequences of non-blank characters, but is inappropriate for use by words like **(**, **.**, **(**, and **."**. Consider the following (flawed) definition of **.(**:

```

: . ( [CHAR] ) WORD COUNT TYPE ; IMMEDIATE

```

This works fine when used in a line like:

```

.( HELLO) 5 .

```

but consider what happens if the user enters an empty string:

```

.( ) 5 .

```

The definition of **.(** shown above would treat the **)** as a leading delimiter, skip it, and continue consuming characters until it located another **)** that followed a non-**)** character, or until the parse area was empty. In the example shown, the **5 .** would be treated as part of the string to be printed.

With **PARSE**, we could write a correct definition of **.(**:

```

: . ( [CHAR] ) PARSE TYPE ; IMMEDIATE

```

This definition avoids the “empty string” anomaly.

- b) **WORD** returns its result as a counted string. This has four bad effects:
- 1) The characters accepted by **WORD** must be copied from the input buffer into a transient buffer, in order to make room for the count character that must be at the beginning of the counted string. The copy step is inefficient, compared to **PARSE**, which leaves the string in the input buffer and doesn't need to copy it anywhere.
  - 2) **WORD** must be careful not to store too many characters into the transient buffer, thus overwriting something beyond the end of the buffer. This adds to the overhead of the copy step. (**WORD** may have to scan a lot of characters before finding the trailing delimiter.)
  - 3) The count character limits the length of the string returned by **WORD** to 255 characters (longer strings can easily be stored in blocks!). This limitation does not exist for **PARSE**.
  - 4) The transient buffer is typically overwritten by the next use of **WORD**.

The need for **WORD** has largely been eliminated by **PARSE** and **PARSE-NAME**. **WORD** is retained for backward compatibility.

#### A.6.2.2030 **PICK**

0 **PICK** is equivalent to **DUP** and 1 **PICK** is equivalent to **OVER**.

#### A.6.2.2125 **REFILL**

**REFILL** is designed to behave reasonably for all possible input sources. If the input source is coming from the user, **REFILL** could still return a false value if, for instance, a communication channel closes so that the system knows that no more input will be available.

#### A.6.2.2150 **ROLL**

2 **ROLL** is equivalent to **ROT**, 1 **ROLL** is equivalent to **SWAP** and 0 **ROLL** is a null operation.

#### A.6.2.2182 **SAVE-INPUT**

**SAVE-INPUT** and **RESTORE-INPUT** allow the same degree of input source repositioning within a text file as is available with **BLOCK** input. **SAVE-INPUT** and **RESTORE-INPUT** “hide the details” of the operations necessary to accomplish this repositioning, and are used the same way with all input sources. This makes it easier for programs to reposition the input source, because they do not have to inspect several variables and take different action depending on the values of those variables.

**SAVE-INPUT** and **RESTORE-INPUT** are intended for repositioning within a single input source; for example, the following scenario is NOT allowed for a Standard Program:

```

: XX
  SAVE-INPUT   CREATE
  S" RESTORE-INPUT" EVALUATE
  ABORT" couldn't restore input"
;

```

This is incorrect because, at the time **RESTORE-INPUT** is executed, the input source is the string via **EVALUATE**, which is not the same input source that was in effect when **SAVE-INPUT** was executed.

The following code is allowed:

```

: XX
  SAVE-INPUT   CREATE
  S" .( Hello)" EVALUATE
  RESTORE-INPUT ABORT" couldn't restore input"
;

```

After **EVALUATE** returns, the input source specification is restored to its previous state, thus **SAVE-INPUT** and **RESTORE-INPUT** are called with the same input source in effect.

In the above examples, the **EVALUATE** phrase could have been replaced by a phrase involving **INCLUDE-FILE** and the same rules would apply.

The standard does not specify what happens if a program violates the above rules. A Standard System might check for the violation and return an exception indication from **RESTORE-INPUT**, or it might fail in an unpredictable way.

The return value from **RESTORE-INPUT** is primarily intended to report the case where the program attempts to restore the position of an input source whose position cannot be restored. The keyboard might be such an input source.

Nesting of **SAVE-INPUT** and **RESTORE-INPUT** is allowed. For example, the following situation works as expected:

```

: XX
  SAVE-INPUT
    S" f1" INCLUDED
      \ The file "f1" includes:
      \   ... SAVE-INPUT ... RESTORE-INPUT ...
      \ End of file "f1"
    RESTORE-INPUT ABORT" couldn't restore input"
  ;

```

In principle, **RESTORE-INPUT** could be implemented to “always fail”, e.g.:

```

: RESTORE-INPUT ( x1 ... xn n -- flag )
  0 ?DO DROP LOOP TRUE
;

```

Such an implementation would not be useful in most cases. It would be preferable for a system to leave **SAVE-INPUT** and **RESTORE-INPUT** undefined, rather than to create a useless implementation. In the absence of the words, the application programmer could choose whether or not to create “dummy” implementations or to work-around the problem in some other way.

Examples of how an implementation might use the return values from **SAVE-INPUT** to accomplish the save/restore function:

Input Source	possible stack values		
block	> <b>IN</b> @	<b>BLK</b> @	2
<b>EVALUATE</b>	> <b>IN</b> @	1	
keyboard	> <b>IN</b> @	1	
text file	> <b>IN</b> @	lo-pos	hi-pos 3

These are examples only; a Standard Program may not assume any particular meaning for the individual stack items returned by **SAVE-INPUT**.

#### A.6.2.2295 **TO**

Typical use:  $x$  **TO** *name*

Some implementations of **TO** do not parse; instead they set a mode flag that is tested by the subsequent execution of *name*. Standard programs must use **TO** as if it parses. Therefore **TO** and *name* must be contiguous and on the same line in the source text.

#### A.6.2.2298 **TRUE**

**TRUE** is equivalent to the phrase 0 **0=**.

#### A.6.2.2405 **VALUE**

Typical use:

```

0 VALUE data
: EXCHANGE ( n1 -- n2 ) data SWAP TO data ;

```

EXCHANGE leaves  $n_1$  in data and returns the prior value  $n_2$ .

#### A.6.2.2440 WITHIN

We describe **WITHIN** without mentioning circular number spaces (an undefined term) or providing the code. Here is a number line with the overflow point ( $o$ ) at the far right and the underflow point ( $u$ ) at the far left:

$$u \text{-----} o$$

There are two cases to consider: either the  $n_2 | u_2 \dots n_3 | u_3$  range straddles the overflow/underflow points or it does not. Lets examine the non-straddle case first:

$$u \text{-----} [ \dots \dots \dots ) \text{-----} o$$

The  $[$  denotes  $n_2 | u_2$ , the  $)$  denotes  $n_3 | u_3$ , and the dots and  $[$  are numbers **WITHIN** the range.  $n_3 | u_3$  is greater than  $n_2 | u_2$ , so the following tests will determine if  $n_1 | u_1$  is **WITHIN**  $n_2 | u_2$  and  $n_3 | u_3$ :

$$n_2 | u_2 \leq n_1 | u_1 \text{ and } n_1 | u_1 < n_3 | u_3$$

In the case where the comparison range straddles the overflow/underflow points:

$$u \dots \dots \dots ) \text{-----} [ \dots \dots \dots o$$

$n_3 | u_3$  is less than  $n_2 | u_2$  and the following tests will determine if  $n_1 | u_1$  is **WITHIN**  $n_2 | u_2$  and  $n_3 | u_3$ :

$$n_2 | u_2 \leq n_1 | u_1 \text{ or } n_1 | u_1 < n_3 | u_3.$$

**WITHIN** must work for both signed and unsigned arguments. One obvious implementation does not work:

```

: WITHIN ( test low high -- flag )
  >R OVER < 0= ( test flag1 ) SWAP R> < ( flag1 flag2 ) AND
;

```

Assume a 16-bit machine, and consider the following test:

```

33000 32000 34000 WITHIN

```

The above implementation returns *false* for that test, even though the unsigned number 33000 is clearly within the range  $\{32000 \dots 34000\}$ .

The problem is that, in the incorrect implementation, the signed comparison  $<$  gives the wrong answer when 32000 is compared to 33000, because when those numbers are treated as signed numbers, 33000 is treated as negative 32536, while 32000 remains positive.

Replacing  $<$  with **U<** in the above implementation makes it work with unsigned numbers, but causes problems with certain signed number ranges; in particular, the test:

```

1 -5 5 WITHIN

```

would give an incorrect answer.

The following implementation works in all cases:

```

: WITHIN ( test low high -- flag )
  OVER - >R - R> U<
;

```

#### A.6.2.2530 [COMPILE]

Typical use: : name2 ... [COMPILE] name1 ... ; IMMEDIATE

#### A.6.2.2535 \

Typical use:

```

5 CONSTANT THAT \ This is a comment about THAT

```

## A.7 The optional Block word set

Early Forth systems ran without a host OS; these are known as native systems. Such systems provide mass storage in blocks of 1024 bytes. The Block Word set includes the most common words for accessing program source and data on disk.

### A.7.2 Additional terms

#### block

Forth systems may use blocks to contain program source. Conventionally such blocks are formatted for editing as 16 lines of 64 characters. Source blocks are often referred to as “screens”.

### A.7.3 Additional usage requirements

#### A.7.3.2 Block buffer regions

While the standard does not address multitasking per se, the items listed in [7.3.2 Block buffer regions](#) that may render block-buffer addresses invalid are due to multitasking considerations. The standard restricts programs such that items that could fail on multitasking systems are not standard usage. It also permits multitasking systems to be declared standard systems.

### A.7.6 Glossary

#### A.7.6.2.2190 SCR

SCR is short for screen.

## A.8 The optional Double-Number word set

Forth systems on 8-bit and 16-bit processors often find it necessary to deal with double-length numbers. But many Forths on small embedded systems do not, and many users of Forth on systems with a cell size of 32-bits or more find that the necessity for double-length numbers is much diminished. Therefore, we have factored the words that manipulate double-length entities into this optional word set.

Please note that the naming convention used in this word set conveys some important information:

1. Words whose names are of the form `2xxx` deal with cell pairs, where the relationship between the cells is unspecified. They may be two-vectors, double-length numbers, or any pair of cells that it is convenient to manipulate together.
2. Words with names of the form `Dxxx` deal specifically with double-length integers.
3. Words with names of the form `Mxxx` deal with some combination of single and double integers. The order in which these appear on the stack is determined by long-standing common practice.

Refer to [A.3.1](#) for a discussion of data types in Forth.

## A.8.6 Glossary

### A.8.6.1.0360 `2CONSTANT`

Typical use: `x1 x2 2CONSTANT name`

### A.8.6.1.0390 `2LITERAL`

Typical use: `: X ... [ x1 x2 ] 2LITERAL ... ;`

### A.8.6.1.0440 `2VARIABLE`

Typical use: `2VARIABLE name`

### A.8.6.1.1070 `D.R`

In `D.R`, the “R” is short for RIGHT.

### A.8.6.1.1140 `D>S`

An alias for `DROP` that conveys the intent to convert a double-cell to a single-cell integer. The original intention of this word was to support signed-number representations other than ~~twos-complement~~ two's complement .

x:2-complement

### A.8.6.1.1820 `M*/`

`M*/` was once described by Chuck Moore as the most useful arithmetic operator in Forth. It is the main workhorse in most computations involving double-cell numbers. Note that some systems allow signed divisors. This can cost a lot in performance on some CPUs. The requirement for a positive divisor has not proven to be a problem.

### A.8.6.1.1830 `M+`

`M+` is the classical method for integrating.

### A.8.6.2.0435 `2VALUE`

Typical use:

```

: fn1 S" filename" ;
fn1 2VALUE myfile
myfile INCLUDED

: fn2 S" filename2" ;
fn2 TO myfile
myfile INCLUDED

```

## A.9 The optional Exception word set

**CATCH** and **THROW** provide a reliable mechanism for handling exceptions, without having to propagate exception flags through multiple levels of word nesting. It is similar in spirit to the “non-local return” mechanisms of many other languages, such as C’s `setjmp()` and `longjmp()`, and LISP’s **CATCH** and **THROW**. In the Forth context, **THROW** may be described as a “multi-level **EXIT**”, with **CATCH** marking a location to which a **THROW** may return.

Several similar Forth “multi-level **EXIT**” exception-handling schemes have been described and used in past years. It is not possible to implement such a scheme using only standard words (other than **CATCH** and **THROW**), because there is no portable way to “unwind” the return stack to a predetermined place.

**THROW** also provides a convenient implementation technique for the standard words **ABORT** and **ABORT"**, allowing an application to define, through the use of **CATCH**, the behavior in the event of a system **ABORT**.

**CATCH** and **THROW** provide a convenient way for an implementation to “clean up” the state of open files if an exception occurs during the text interpretation of a file with **INCLUDE-FILE**. The implementation of **INCLUDE-FILE** may guard (with **CATCH**) the word that performs the text interpretation, and if **CATCH** returns an exception code, the file may be closed and the exception re**THROW**n so that the files being included at an outer nesting level may be closed also. Note that the standard allows, but does not require, **INCLUDE-FILE** to close its open files if an exception occurs. However, it does require **INCLUDE-FILE** to unnest the input source specification if an exception is **THROW**n.

### A.9.3 Additional usage requirements

One important use of an exception handler is to maintain program control under many conditions which **ABORT**. This is practicable only if a range of codes is reserved. Note that an application may overload many standard words in such a way as to **THROW** ambiguous conditions not normally **THROW**n by a particular system.

#### A.9.3.6 Exception handling

The method of accomplishing this coupling is implementation dependent. For example, **LOAD** could “know” about **CATCH** and **THROW** (by using **CATCH** itself, for example), or **CATCH** and **THROW** could “know” about **LOAD** (by maintaining input source nesting information in a data structure known to **THROW**, for example). Under these circumstances it is not possible for a Standard Program to define words such as **LOAD** in a completely portable way.

### A.9.6 Glossary

#### A.9.6.1.2275 **THROW**

If **THROW** is executed with a non zero argument, the effect is as if the corresponding **CATCH** had returned it. In that case, the stack depth is the same as it was just before **CATCH** began execution. The values of the  $i * x$  stack arguments could have been modified arbitrarily during the execution of  $xt$ . In general, nothing useful may be done with those stack items, but since their number is known (because the stack depth is deterministic), the application may **DROP** them to return to a predictable stack state.

Typical use:

```

: could-fail ( -- char )
  KEY DUP [CHAR] Q = IF 1 THROW THEN ;

: do-it ( a b -- c) 2DROP could-fail ;

: try-it ( --)
  1 2 [' ] do-it CATCH IF
    ( x1 x2 ) 2DROP ." There was an exception" CR
  ELSE ." The character was " EMIT CR
  THEN
;

: retry-it ( -- )
  BEGIN 1 2 [' ] do-it CATCH WHILE
    ( x1 x2 ) 2DROP ." Exception, keep trying" CR
  REPEAT ( char )
    ." The character was " EMIT CR
  ;

```

## A.10 The optional Facility word set

### A.10.6 Glossary

#### A.10.6.1.1755 KEY?

The committee has gone around several times on the stack effects. Whatever is decided will violate somebody's practice and penalize some machine. This way doesn't interfere with type-ahead on some systems, while requiring the implementation of a single-character buffer on machines where polling the keyboard inevitably results in the destruction of the character.

Use of **KEY** or **KEY?** indicates that the application does not wish to process non-character events, so they are discarded, in anticipation of eventually receiving a valid character. Applications wishing to handle non-character events must use **EKEY** and **EKEY?**. It is possible to mix uses of **KEY?/KEY** and **EKEY?/EKEY** within a single application, but the application must use **KEY?** and **KEY** only when it wishes to discard non-character events until a valid character is received.

#### A.10.6.2.0135 +FIELD

**+FIELD** is not required to align items. This is deliberate and allows the construction of unaligned data structures for communication with external elements such as a hardware register map or protocol packet. Field alignment has been left to the appropriate **xFIELD:** definition.

#### A.10.6.2.0763 BEGIN-STRUCTURE

There are two schools of thought regarding named data structures: name first and name last. The name last school can define a named data structure as follows:

```

0          \ initial total byte count
1 CELLS +FIELD p.x \ A single cell filed named p.x
1 CELLS +FIELD p.y \ A single cell field named p.y
CONSTANT point    \ save structure size

```

While the name first school would define the same data structure as:

```

BEGIN-STRUCTURE point \ create the named structure
  1 CELLS +FIELD p.x \ A single cell field named p.x
  1 CELLS +FIELD p.y \ A single cell field named p.y
END-STRUCTURE

```

Although many systems provide a name first structure there is no common practice to the words used. The words **BEGIN-STRUCTURE** and **END-STRUCTURE** have been defined as a means of providing a portable notation that does not conflict with existing systems.

The field defining words (`xFIELD:` and **+FIELD**) are defined so they can be used by both schools. Compatibility between the two schools comes from defining a new stack item *struct-sys*, which is implementation dependent and can be 0 or more cells. The name first school would provide an address (*addr*) as the *struct-sys* parameter, while the name last school would defined *struct-sys* as being empty.

Executing the name of the data structure, returns the size of the data structure. This allows the data structure to be used within another data structure:

```

BEGIN-STRUCTURE point \ -- a-addr 0 ; -- lenp
  FIELD: p.x \ -- a-addr cell
  FIELD: p.y \ -- a-addr cell*2
END-STRUCTURE

```

```

BEGIN-STRUCTURE rect \ -- a-addr 0 ; -- lenr
  point +FIELD r.tlhc \ -- a-addr cell*2
  point +FIELD r.brhc \ -- a-addr cell*4
END-STRUCTURE

```

Alignment:

In practice, structures are used for two different purposes with incompatible requirements:

- a) For collecting related internal-use data into a convenient “package” that can be referred to by a single “handle”. For this use, alignment is important, so that efficient native fetch and store instructions can be used.
- b) For mapping external data structures like hardware register maps and protocol packets. For this use, automatic alignment is inappropriate, because the alignment of the external data structure often doesn’t match the rules for a given processor.

Many languages cater for the first use, but ignore the second. This leads to various customized solutions, usage requirements, portability problems, bugs, etc. **+FIELD** is defined to be non-aligning, while the named field defining words (`xFIELD:`) are aligning. This is intentional and allows for both uses.

The standard currently defines an aligned field defining word for each of the standard data types:

**CFIELD** : a character  
**FIELD** : a native integer (single cell)  
**FFIELD** : a native float  
**SFFIELD** : a 32 bit float  
**DFFIELD** : a 64 bit float

Although this is a sufficient set, most systems provide facilities to define field defining words for standard data types.

Future:

The following cannot be defined until the required addressing has been defined. The names should be considered reserved until then.

**BFIELD** : 1 byte (8 bit) field  
**WFIELD** : 16 bit field  
**LFIELD** : 32 bit field  
**XFIELD** : 64 bit field

#### A.10.6.2.1305 **EKEY**

For some input devices, such as keyboards, more information is available than can be returned by a single execution of **KEY**. **EKEY** provides a standard word to access a system-dependent set of events.

**EKEY** and **EKEY?** are implementation specific; no assumption can be made regarding the interaction between the pairs **EKEY/EKEY?** and **KEY/KEY?**. This standard does not define a timing relationship between **KEY?** and **EKEY?**. Undefined results may be avoided by using only one pairing of **KEY/KEY?** or **EKEY/EKEY?** in a program for each input stream.

**EKEY** assumes no particular numerical correspondence between particular event code values and the values representing standard characters. On some systems, this may allow two separate keys that correspond to the same standard character to be distinguished from one another. A standard program may only interpret the results of **EKEY** via the translation words provided for that purpose (**EKEY>CHAR** and **EKEY>FKEY**).

See: [A.6.1.1750 KEY](#), [10.6.2.1306 EKEY>CHAR](#) and [10.6.2.1306.40 EKEY>FKEY](#).

#### A.10.6.2.1306 **EKEY>CHAR**

**EKEY>CHAR** translates a keyboard event into the corresponding member of the character set, if such a correspondence exists for that event.

It is possible that several different keyboard events may correspond to the same character, and other keyboard events may correspond to no character.

#### A.10.6.2.1306.40 **EKEY>FKEY**

**EKEY** produces an abstract cell type for a keyboard event (e.g., a keyboard scan code). **EKEY>FKEY** checks if such an event corresponds to a special (non-graphic) key press, and if so, returns a code for the special key press. The encoding of special keys (returned by **EKEY>FKEY**) may be different from the encoding of these keys as keyboard events (input to **EKEY>FKEY**).

Typical Use:

```
... EKEY EKEY>FKEY IF
CASE
```

```

K-UP OF ... ENDOF
K-F1 OF ... ENDOF
K-LEFT K-SHIFT-MASK OR K-CTRL-MASK OR OF ... ENDOF
...
ENDCASE
ELSE
...
THEN

```

The codes for the special keys are system-dependent, but this standard provides words for getting the key codes for a number of keys:

Word	Key	Word	Key
<b>K-F1</b>	F1	<b>K-LEFT</b>	cursor left
<b>K-F2</b>	F2	<b>K-RIGHT</b>	cursor right
<b>K-F3</b>	F3	<b>K-UP</b>	cursor up
<b>K-F4</b>	F4	<b>K-DOWN</b>	cursor down
<b>K-F5</b>	F5	<b>K-HOME</b>	home or Pos1
<b>K-F6</b>	F6	<b>K-END</b>	End
<b>K-F7</b>	F7	<b>K-PRIOR</b>	PgUp or Prior
<b>K-F8</b>	F8	<b>K-NEXT</b>	PgDn or Next
<b>K-F9</b>	F9	<b>K-INSERT</b>	Insert
<b>K-F10</b>	F10	<b>K-DELETE</b>	Delete
<b>K-F11</b>	F11		
<b>K-F12</b>	F12		

In addition, you can get codes for shifted variants of these keys by **ORing** with **K-SHIFT-MASK**, **K-CTRL-MASK** and/or **K-ALT-MASK**, e.g. **K-CTRL-MASK K-ALT-MASK OR K-DELETE OR**. The masks for the shift keys are:

Word	Key
<b>K-SHIFT-MASK</b>	Shift
<b>K-CTRL-MASK</b>	Ctrl
<b>K-ALT-MASK</b>	Alt

Note that not all of these keys are available on all systems, and not all combinations of keys and shift keys are available. Therefore programs should be written such that they continue to work (although less conveniently or with less functionality) if these key combinations cannot be produced.

#### A.10.6.2.1325 **EMIT?**

An indefinite delay is a device related condition, such as printer off-line, that requires operator intervention before the device will accept new data.

#### A.10.6.2.1518 **FIELD:**

Create an aligned single-cell field in a data structure.

The various **xFIELD:** words provide for different alignment and size allocation.

The **xFIELD:** words could be defined as:

```

: FIELD: ( n1 "name" -- n2 ; addr1 -- addr2 ) ALIGNED 1 CELLS +FIELD ;
: CFIELD: ( n1 "name" -- n2 ; addr1 -- addr2 ) 1 CHARS +FIELD ;
: FFIELD: ( n1 "name" -- n2 ; addr1 -- addr2 ) FALIGNED 1 FLOATS +FIELD ;
: SFFIELD: ( n1 "name" -- n2 ; addr1 -- addr2 ) SFALIGNED 1 SFLOATS +FIELD ;
: DFFIELD: ( n1 "name" -- n2 ; addr1 -- addr2 ) DFALIGNED 1 DFLOATS +FIELD ;

```

#### A.10.6.2.1905 MS

Although their frequencies vary, every system has a clock. Since many programs need to time intervals, this word is offered. Use of milliseconds as an internal unit of time is a practical “least common denominator” external unit. It is assumed implementors will use “clock ticks” (whatever size they are) as an internal unit and convert as appropriate.

#### A.10.6.2.2292 TIME&DATE

Most systems have a real-time clock/calendar. This word gives portable access to it.

## A.11 The optional File-Access word set

### A.11.3 Additional usage requirements

#### A.11.3.2 Blocks in files

Many systems reuse file identifiers; when a file is closed, a subsequently opened file may be given the same identifier. If the original file has blocks still in block buffers, these will be incorrectly associated with the newly opened file with disastrous results. The block buffer system must be flushed to avoid this.

#### A.11.3.4 Other transient regions

Additional transient buffers are provided for use by **S"** and **S\**". The buffers should be able to store two consecutive strings, thus allowing the command line:

```
S" name1 " S" name2 " RENAME-FILE
```

The buffers may be implemented in a circular arrangement, where a string is placed into the next available buffer. When there are no buffers available, the oldest buffer is overwritten.

**S"** and **S\**" may share the same buffers.

The list of words using memory in transient regions is extended to include **11.6.1.2165 S"** and **11.6.2.2266 S\**". See **3.3.3.6 Other transient regions**.

### A.11.6 Glossary

#### A.11.6.1.0765 BIN

Some operating systems require that files be opened in a different mode to access their contents as an unstructured stream of binary data rather than as a sequence of lines.

The arguments to **READ-FILE** and **WRITE-FILE** are arrays of character storage elements, each element consisting of at least 8 bits. The committee intends that, in **BIN** mode, the contents of these storage elements can be written to a file and later read back without alteration.

**A.11.6.1.1010 CREATE-FILE**

Typical use:

```
: X ... S" TEST.FTH" R/W CREATE-FILE ABORT" CREATE-FILE FAILED" ;
```

**A.11.6.1.1717 INCLUDE-FILE**

Here are two implementation alternatives for saving the input source specification in the presence of text file input:

- 1) Save the file position (as returned by **FILE-POSITION**) of the beginning of the line being interpreted. To restore the input source specification, seek to that position and re-read the line into the input buffer.
- 2) Allocate a separate line buffer for each active text input file, using that buffer as the input buffer. This method avoids the “seek and reread” step, and allows the use of “pseudo-files” such as pipes and other sequential-access-only communication channels.

**A.11.6.1.1718 INCLUDED**

Typical use: ... S" filename" INCLUDED ...

**A.11.6.1.1970 OPEN-FILE**

Typical use:

```
: X ... S" TEST.FTH" R/W OPEN-FILE ABORT" OPEN-FILE FAILED" ... ;
```

**A.11.6.1.2080 READ-FILE**

A typical sequential file-processing algorithm might look like:

```
BEGIN                ( )
... READ-FILE THROW ( length )
?DUP WHILE          ( length )
...                 ( )
REPEAT              ( )
```

In this example, **THROW** is used to handle exception conditions, which are reported as non-zero values of the *ior* return value from **READ-FILE**. End-of-file is reported as a zero value of the “length” return value.

**A.11.6.1.2090 READ-LINE**

Implementations are allowed to store the line terminator in the memory buffer in order to allow the use of line reading functions provided by host operating systems, some of which store the terminator. Without this provision, a transient buffer might be needed. The two-character limitation is sufficient for the vast majority of existing operating systems. Implementations on host operating systems whose line terminator sequence is longer than two characters may have to take special action to prevent the storage of more than two terminator characters.

Standard Programs may not depend on the presence of any such terminator sequence in the buffer.

A typical line-oriented sequential file-processing algorithm might look like:

```
BEGIN                ( )
... READ-LINE THROW ( length not-eof-flag )
```

```

WHILE                ( length )
  ...                ( )
REPEAT DROP         ( )

```

**READ-LINE** needs a separate end-of-file flag because empty (zero-length) lines are a routine occurrence, so a zero-length line cannot be used to signify end-of-file.

#### A.11.6.1.2165 **S"**

Typical use: ... **S" ccc" ...**

The interpretation semantics for **S"** are intended to provide a simple mechanism for entering a string in the interpretation state. Since an implementation may choose to provide only one buffer for interpreted strings, an interpreted string is subject to being overwritten by the next execution of **S"** in interpretation state. It is intended that no standard words other than **S"** should in themselves cause the interpreted string to be overwritten. However, since words such as **EVALUATE**, **LOAD**, **INCLUDE-FILE** and **INCLUDED** can result in the interpretation of arbitrary text, possibly including instances of **S"**, the interpreted string may be invalidated by some uses of these words.

When the possibility of overwriting a string can arise, it is prudent to copy the string to a “safe” buffer allocated by the application.

#### A.11.6.2.1714 **INCLUDE**

Typical use:

```
INCLUDE filename
```

#### A.11.6.2.2144.10 **REQUIRE**

Typical use:

```
REQUIRE filename
```

#### A.11.6.2.2144.50 **REQUIRED**

Typical use:

```
S" filename" REQUIRED
```

## A.12 The optional Floating-Point word set

The current base for floating-point input must be **DECIMAL**. Floating-point input is not allowed in an arbitrary base. All floating-point numbers to be interpreted by a standard system must contain the exponent indicator “E” (see [12.3.7 Text interpreter input number conversion](#)). Consensus in the committee deemed this form of floating-point input to be in more common use than the alternative that would have a floating-point input mode that would allow numbers with embedded decimal points to be treated as floating-point numbers.

Although the format and precision of the significand and the format and range of the exponent of a floating-point number are implementation defined in Forth-2012, the Floating-Point Extensions word set contains the words **DF@**, **SF@**, **DF!**, and **SF!** for fetching and storing double- and single-precision IEEE floating-point-format numbers to memory. The IEEE floating-point format is commonly used by numeric math co-processors and for exchange of floating-point data between programs and systems.

## A.12.3 Additional usage requirements

### A.12.3.5 Address alignment

In defining custom floating-point data structures, be aware that **CREATE** doesn't necessarily leave the data space pointer aligned for various floating-point data types. Programs may comply with the requirement for the various kinds of floating-point alignment by specifying the appropriate alignment both at compile-time and execution time. For example:

```

: FCONSTANT ( F: r -- )
  CREATE FALIGN HERE 1 FLOATS ALLOT F!
DOES> ( F: -- r ) FALIGNED F@ ;

```

### A.12.3.7 Text interpreter input number conversion

The committee has more than once received the suggestion that the text interpreter in standard Forth systems should treat numbers that have an embedded decimal point, but no exponent, as floating-point numbers rather than double cell numbers. This suggestion, although it has merit, has always been voted down because it would break too much existing code; many existing implementations put the full digit string on the stack as a double number and use other means to inform the application of the location of the decimal point.

## A.12.6 Glossary

### A.12.6.1.0558 >FLOAT

**>FLOAT** enables programs to read floating-point data in legible ASCII format. It accepts a much broader syntax than does the text interpreter since the latter defines rules for composing source programs whereas **>FLOAT** defines rules for accepting data. **>FLOAT** is defined as broadly as is feasible to permit input of data from Forth-2012 systems as well as other widely used standard programming environments.

This is a synthesis of common FORTRAN practice. Embedded spaces are explicitly forbidden in much scientific usage, as are other field separators such as comma or slash.

While **>FLOAT** is not required to treat a string of blanks as zero, this behavior is strongly encouraged, since a future version of this standard may include such a requirement.

### A.12.6.1.1492 FCONSTANT

Typical use: `r FCONSTANT name`

### A.12.6.1.1552 FLITERAL

Typical use: `: X... [ ... ( r ) ] FLITERAL ... ;`

### A.12.6.1.1630 FVARIABLE

Typical use: `FVARIABLE name`

### A.12.6.1.2143 REPRESENT

This word provides a primitive for floating-point display. Some floating-point formats, including those specified by IEEE-754, allow representations of numbers outside of an implementation-defined range. These include plus and minus infinities, denormalized numbers, and others. In these cases we

expect that **REPRESENT** will usually be implemented to return appropriate character strings, such as “+infinity” or “nan”, possibly truncated.

#### A.12.6.2.1427 **F**.

For example, `1E3 F.` displays `1000.`

#### A.12.6.2.1489 **FATAN2**

**FSINCOS** and **FATAN2** are a complementary pair of operators which convert angles to 2-vectors and vice-versa. They are essential to most geometric and physical applications since they correctly and unambiguously handle this conversion in all cases except null vectors, even when the tangent of the angle would be infinite.

**FSINCOS** returns a Cartesian unit vector in the direction of the given angle, measured counter-clockwise from the positive X-axis. The order of results on the stack, namely  $y$  underneath  $x$ , permits the 2-vector data type to be additionally viewed and used as a ratio approximating the tangent of the angle. Thus the phrase **FSINCOS F/** is functionally equivalent to **FTAN**, but is useful over only a limited and discontinuous range of angles, whereas **FSINCOS** and **FATAN2** are useful for all angles.

The argument order for **FATAN2** is the same, converting a vector in the conventional representation to a scalar angle. Thus, for all angles, **FSINCOS FATAN2** is an identity within the accuracy of the arithmetic and the argument range of **FSINCOS**. Note that while **FSINCOS** always returns a valid unit vector, **FATAN2** will accept any non-null vector. An ambiguous condition exists if the vector argument to **FATAN2** has zero magnitude.

#### A.12.6.2.1516 **FEXPM1**

This function allows accurate computation when its arguments are close to zero, and provides a useful base for the standard exponential functions. Hyperbolic functions such as  $\sinh(x)$  can be efficiently and accurately implemented by using **FEXPM1**; accuracy is lost in this function for small values of  $x$  if the word **FEXP** is used.

An important application of this word is in finance; say a loan is repaid at 15% per year; what is the daily rate? On a computer with single-precision (six decimal digit) accuracy:

1. Using **FLN** and **FEXP**:

**FLN** of 1.15 = 0.139762,  
 divide by 365 = 3.82910E-4,  
 form the exponent using **FEXP** = 1.00038, and  
 subtract one (1) and convert to percentage = 0.038%.

Thus we only have two-digit accuracy.

2. Using **FLNP1** and **FEXPM1**:

**FLNP1** of 0.15 = 0.139762, (this is the same value as in the first example, although with the argument closer to zero it may not be so)  
 divide by 365 = 3.82910E-4,  
 form the exponent and subtract one (1) using **FEXPM1** = 3.82983E-4, and  
 convert to percentage = 0.0382983%.

This calculation method allows the hyperbolic functions to be computed with six-digit accuracy. For example, `sinh` can be defined as:

```
: FSINH ( r1 -- r2 )
  FEXPM1 FDUP FDUP 1.0E0 F+ F/ F+ 2.0E0 F/ ;
```

#### A.12.6.2.1554 **FLNP1**

This function allows accurate compilation when its arguments are close to zero, and provides a useful base for the standard logarithmic functions. For example, **FLN** can be implemented as:

```
: FLN 1.0E0 F- FLNP1 ;
```

See: [A.12.6.2.1516 FEXPM1](#).

#### A.12.6.2.1640 **F~**

This provides the three types of “floating point equality” in common use — “close” in absolute terms, exact equality as represented, and “relatively close”.

## A.13 The optional Locals word set

### A.13.3 Additional usage requirements

Rule [13.3.3.2d](#) could be relaxed without affecting the integrity of the rest of this structure. [13.3.3.2c](#) could not be.

[13.3.3.2b](#) forbids the use of the data stack for local storage because no usage rules have been articulated for programmer users in such a case. Of course, if the data stack is somehow employed in such a way that there are no usage rules, then the locals are invisible to the programmer, are logically not on the stack, and the implementation conforms.

Access to previously declared local variables is prohibited by Section [13.3.3.2d](#) until any data placed onto the return stack by the application has been removed, due to the possible use of the return stack for storage of locals.

Authorization for a Standard Program to manipulate the return stack (e.g., via **>R R>**) while local variables are active overly constrains implementation possibilities. The consensus of users of locals was that Local facilities represent an effective functional replacement for return stack manipulation, and restriction of standard usage to only one method was reasonable.

Access to Locals within **DO...LOOP**s is expressly permitted as an additional requirement of conforming systems by Section [13.3.3.2g](#). Although words, such as **(LOCAL)**, written by a System Implementor, may require inside knowledge of the internal structure of the return stack, such knowledge is not required of a user of compliant Forth systems.

### A.13.6 Glossary

#### A.13.6.2.2550 **{ :**

The Forth 94 Technical Committee was unable to identify any common practice for locals. It provided a way to define locals and a method of parsing them in the hope that a common practice would emerge.

Since then, common practice has emerged. Most implementations that provide **(LOCAL)** and **LOCALS|** also provide some form of the `{ ... }` notation; however, the phrase `{ ... }` conflicts with other systems. The `{ : ... : }` notation is a compromise to avoid name conflicts.

The notation provides for different kinds of local: those that are initialized from the data stack at run-time, uninitialized locals, and outputs. Initialized locals are separated from uninitialized locals by `'|'`. The definition of locals is terminated by `'--'` or `': }'`.

All text between `'--'` and `': }'` is ignored. This eases documentation by allowing a complete stack comment in the locals definition.

The `'|'` (ASCII \$7C) character is widely used as the separator between local arguments and local values. Some implementations have used `'\'` (ASCII \$5C) or `'|'` (\$A6). Systems are free to continue to provide these alternative separators. However, only the recognition of the `'|'` separator is mandatory. Therefore portable programs must use the `'|'` separator.

A number of systems extend the locals notation in various ways. Some of these extensions may emerge as common practice. This standard has reserved the notation used by these extensions to avoid difficulties when porting code to these systems. In particular local names ending in `':'` (colon), `'['` (open bracket), or `'^'` (caret) are reserved.

## A.14 The optional Memory-Allocation word set

The Memory-Allocation word set provides a means for acquiring memory other than the contiguous data space that is allocated by **ALLOT**. In many operating system environments it is inappropriate for a process to pre-allocate large amounts of contiguous memory (as would be necessary for the use of **ALLOT**). The Memory-Allocation word set can acquire memory from the system at any time, without knowing in advance the address of the memory that will be acquired.

## A.15 The optional Programming-Tools word set

These words have been in widespread common use since the earliest Forth systems.

Although there are environmental dependencies intrinsic to programs using an assembler, virtually all Forth systems provide such a capability. Insofar as many Forth programs are intended for real-time applications and are intrinsically non-portable for this reason, the committee believes that providing a standard window into assemblers is a useful contribution to Forth programmers.

Similarly, the programming aids **DUMP**, etc., are valuable tools even though their specific formats will differ between CPUs and Forth implementations. These words are primarily intended for use by the programmer, and are rarely invoked in programs.

One of the original aims of Forth was to erase the boundary between “user” and “programmer” — to give all possible power to anyone who had occasion to use a computer. Nothing in the above labeling or remarks should be construed to mean that this goal has been abandoned.

### A.15.3.1 Name tokens

Name tokens are an abstract data type identifying named words. You can use words such as **NAME>STRING** to get information out of name tokens.

## A.15.6 Glossary

### A.15.6.1.0220 **.S**

**.S** is a debugging convenience found on almost all Forth systems. It is universally mentioned in Forth texts.

### A.15.6.1.2194 **SEE**

**SEE** acts as an on-line form of documentation of words, allowing modification of words by decompiling and regenerating with appropriate changes.

### A.15.6.1.2465 **WORDS**

**WORDS** is a debugging convenience found on almost all Forth systems. It is universally referred to in Forth texts.

### A.15.6.2.0470 **;CODE**

Typical use: `: namex ... <create> ... ;CODE ...`

where `namex` is a defining word, and `<create>` is **CREATE** or any user defined word that calls **CREATE**.

### A.15.6.2.0930 **CODE**

Some Forth systems implement the assembly function by adding an **ASSEMBLER** word list to the search order, using the text interpreter to parse a postfix assembly language with lexical characteristics similar to Forth source code. Typically, in such systems, assembly ends when a word `END-CODE` is interpreted.

### A.15.6.2.1015 **CS-PICK**

The intent is to copy a *dest* on the control-flow stack so that it can be resolved more than once. For example:

```
\ Conditionally transfer control to beginning of
\ loop. This is similar in spirit to C's "continue"
\ statement.

: ?REPEAT ( dest -- dest ) \ Compilation
  ( flag -- ) \ Execution
  0 CS-PICK POSTPONE UNTIL
; IMMEDIATE

: XX ( -- ) \ Example use of ?REPEAT
BEGIN
  ...
  flag ?REPEAT ( Go back to BEGIN if flag is false )
  ...
  flag ?REPEAT ( Go back to BEGIN if flag is false )
  ...
  flag UNTIL ( Go back to BEGIN if flag is false )
;
```

**A.15.6.2.1020 CS-ROLL**

The intent is to modify the order in which the *origs* and *dests* on the control-flow stack are to be resolved by subsequent control-flow words. For example, **WHILE** could be implemented in terms of **IF** and **CS-ROLL**, as follows:

```

: WHILE ( dest -- orig dest )
  POSTPONE IF 1 CS-ROLL
; IMMEDIATE

```

**A.15.6.2.1580 FORGET**

Typical use: ... **FORGET** *name* ...

**FORGET** *name* tries to infer the previous dictionary state from *name*; this is not always possible. As a consequence, **FORGET** *name* removes *name* and all following words in the name space.

See **A.6.2.1850** **MARKER**.

**A.15.6.2.1908 N>R**

An implementation may store the stack items in any manner. It may store them on the return stack, in any order. A stack-constrained system may prefer to use a buffer to store the items and place a reference to the buffer on the return stack.

See: **6.2.2182** **SAVE-INPUT**, **6.2.2148** **RESTORE-INPUT**, **16.6.1.1647** **GET-ORDER**, **16.6.1.2197** **SET-ORDER**.

**A.15.6.2.1909.10 NAME>COMPILE**

In a traditional *xt*+immediate-flag system, the *x xt* returned by **NAME>COMPILE** is typically *xt1 xt2*, where *xt1* is the *xt* of the word under consideration, and *xt2* is the *xt* of **EXECUTE** (for immediate words) or **COMPILE**, (for words with default compilation semantics).

If you want to **POSTPONE** *nt*, you can do so with

```

NAME>COMPILE SWAP POSTPONE LITERAL COMPILE,

```

**A.15.6.2.2297 TRAVERSE-WORDLIST**

Typical use:

```

: WORDS-COUNT ( x nt -- x' f ) DROP 1+ TRUE ;
0 ' WORDS-COUNT FORTH-WORDLIST TRAVERSE-WORDLIST .

```

prints a count of the number of words in the **FORTH-WORDLIST**.

```

: ALL-WORDS NAME>STRING CR TYPE TRUE ;
' ALL-WORDS GET-CURRENT TRAVERSE-WORDLIST

```

prints the names of words in the current compilation wordlist.

```

: CONTAINS-STRING
  NAME>STRING 2OVER SEARCH IF CR TYPE THEN FALSE ;
S" COM" ' CONTAINS-STRING GET-CURRENT TRAVERSE-WORDLIST

```

prints the name of a word containing the string "COM", if it exists, and then terminates.

**A.15.6.2.2531 [ELSE]**

Typical use: ... *flag* [IF] ... [ELSE] ... [THEN] ...

**A.15.6.2.2532 [IF]**

Typical use: ... *flag* [IF] ... [ELSE] ... [THEN] ...

**A.15.6.2.2533 [THEN]**

Typical use: ... *flag* [IF] ... [ELSE] ... [THEN] ...

Software that runs in several system environments often contains some source code that is environmentally dependent. Conditional compilation — the selective inclusion or exclusion of portions of the source code at compile time — is one technique that is often used to assist in the maintenance of such source code.

Conditional compilation is sometimes done with “smart comments” — definitions that either skip or do not skip the remainder of the line based on some test. For example:

```
\ If 16-Bit? contains TRUE, lines preceded by 16BIT\  
\ will be skipped. Otherwise, they will not be skipped.  
  
VARIABLE 16-BIT?  
  
: 16BIT\ ( -- ) 16-BIT? @ IF POSTPONE \ THEN  
; IMMEDIATE
```

This technique works on a line by line basis, and is good for short, isolated variant code sequences.

More complicated conditional compilation problems suggest a nestable method that can encompass more than one source line at a time. The words included in the optional Programming tools extensions word set are useful for this purpose.

## A.16 The optional Search-Order word set

The search-order word set is intended to be a portable “construction set” from which search-order words may be built. **ALSO/ONLY** or the various “vocabulary” schemes supported by the major Forth vendors can be defined in terms of the primitive search-order word set.

The encoding for word list identifiers *wid* might be a small-integer index into an array of word-list definition records, the data-space address of such a record, a user-area offset, the execution token of a sealed vocabulary, the link-field address of the first definition in a word list, or anything else. It is entirely up to the system implementor.

### A.16.2 Additional terms and notation

#### search order

Note that the use of the term “list” does not necessarily imply implementation as a linked list

## A.16.3 Additional usage requirements

### A.16.3.3 Finding definition names

In other words, the following is not guaranteed to work:

```
: FOO ... [ ... SET-CURRENT ] ... RECURSE ...
; IMMEDIATE
```

**RECURSE**, **;** (semicolon), and **IMMEDIATE** may or may not need information stored in the compilation word list.

## A.16.6 Glossary

### A.16.6.1.2192 SEARCH-WORDLIST

When **SEARCH-WORDLIST** fails to find the word, it does not return the string, unlike **FIND**. This is in accordance with the general principle that Forth words consume their arguments.

## A.17 The optional String word set

### A.17.6 Glossary

#### A.17.6.1.0245 /STRING

**/STRING** is used to remove or add characters relative to the current position in the character string. Positive values of  $n$  will exclude characters from the string while negative values of  $n$  will include characters to the left of the string.

```
S" ABC" 2 /STRING 2DUP TYPE \ outputs "C"
-1 /STRING TYPE \ outputs "BC"
```

#### A.17.6.1.0910 CMOVE

If  $c\text{-}addr_2$  lies within the source region (i.e., when  $c\text{-}addr_2$  is not less than  $c\text{-}addr_1$  and  $c\text{-}addr_2$  is less than the quantity  $c\text{-}addr_1$  u **CHARS +**), memory propagation occurs.

Assume a character string at address 100: "ABCD". Then after

```
100 DUP CHAR+ 3 CMOVE
```

the string at address 100 is "AAAA".

See [A.6.1.1900 MOVE](#).

#### A.17.6.1.0920 CMOVE>

If  $c\text{-}addr_1$  lies within the destination region (i.e., when  $c\text{-}addr_1$  is greater than or equal to  $c\text{-}addr_2$  and  $c\text{-}addr_2$  is less than the quantity  $c\text{-}addr_1$  u **CHARS +**), memory propagation occurs.

Assume a character string at address 100: "ABCD". Then after

```
100 DUP CHAR+ SWAP 3 CMOVE>
```

the string at address 100 is "DDDD".

See [A.6.1.1900 MOVE](#).

**A.17.6.1.2212 SLITERAL**

The current functionality of **6.1.2165 S"** may be provided by the following definition:

```
: S" ( "ccc" -- )
  [CHAR] " PARSE  POSTPONE SLITERAL
; IMMEDIATE
```

**A.17.6.2.2255 SUBSTITUTE**

Many applications need to be able to perform text substitution, for example:

Your balance at *<time>* on *<date>* is *<currencyvalue>*.

Translation of a sentence or message from one language to another may result in changes to the displayed parameter order. The example, the Afrikaans translation of this sentence requires a different order:

Jou balans op *<date>* om *<time>* is *<currencyvalue>*.

The words **SUBSTITUTE** and **REPLACES** provide for this requirements by defining a text substitution facility. For example, we can provide an initial string in the form:

```
Your balance at %time% on %date% is %currencyvalue%.
```

The % is used as delimiters for the substitution name. The text “currencyvalue”, “date” and “time” are text substitutions, where the replacement text is defined by **REPLACES**:

```
: date S" 07/Sep/2017" ;
: time S" 10:19" ;
date S" date" REPLACES
time S" time" REPLACES
```

The substitution name “date” is defined to be replaced with the string “07/Sep/2017” and “time” to be replaced with “10:19”. Thus **SUBSTITUTE** would produce the string:

```
Your balance at 10:19 on 07/Sep/2017 is %currencyvalue%.
```

As the substitution name “currencyvalue” has not been defined, it is left unchanged in the resulting string.

The return value *n* is nonnegative on success and indicates the number of substitutions made. In the above example, this would be two. A negative value indicates that an error occurred. As substitution is not recursive, the return value could be used to provide a recursive substitution.

Implementation of **SUBSTITUTE** may be considered as being equivalent to a wordlist which is searched. If the substitution name is found, the word is executed, returning a substitution string. Such words can be deferred or multiple wordlists can be used. The implementation techniques required are similar to those used by **ENVIRONMENT?**. There is no provision for changing the delimiter character, although a system may provide system-specific extensions.

**A.18 The optional Extended-Character word set**

Forth defines graphic and control characters from the ASCII character set. ASCII was originally designed for the English language. However, most western languages fit somewhat into the Forth framework, since

a single byte is sufficient to encode all characters in each language, although different languages may use different encodings; Latin-1 and Latin-15 are widely used. For other languages, different character sets have to be used, several of which are variable-width. Currently, the most popular representative of the variable-width character sets is UTF-8.

Many Forth systems today are case insensitive, to accept lower case standard words. It is sufficient to be case insensitive for the ASCII subset to make this work — this saves a large code mapping table for comparison of other symbols. Case is mostly an issue of European languages (Latin, Greek, and Cyrillic), but similar issues exist between traditional and simplified Chinese (finally being dealt with by Unihan), and between different Latin code pages in the Universal Character Set (UCS), e.g., full width vs. normal half width Latin letters.

Furthermore, UCS allows composition of glyphs and has direct encoding for composed glyphs, which look the same, but have different encodings. This is not a problem for a Forth system to solve.

Some encodings (not UTF-8) might give surprises when you use a case insensitive ASCII-compare that's 8-bit safe, but not aware of the current encoding.

The xchar word set does not address problems that come from using multiple different encodings and switching or converting between them. It is good practice for a system implementing xchar to support UTF-8.

## **A.18.6 Glossary**

### **A.18.6.2.0895 CHAR**

The behavior of the extended version of **CHAR** is fully backward compatible with **6.1.0895 CHAR**.

## Annex B (informative) Bibliography

### Industry standards

- Forth-77 Standard*, Forth Users Group, FST-780314.  
*Forth-78 Standard*, Forth International Standards Team.  
*Forth-79 Standard*, Forth Standards Team.  
*Forth-83 Standard* and Appendices, Forth Standards Team.

The standards referenced in this section were developed by the Forth Standards Team, a volunteer group which included both implementors and users. This was a volunteer organization operating under its own charter and without any formal ties to ANSI, IEEE or any similar standards body.

The following standards were developed under the auspices of ANSI. The committee drawing up the ANSI standard included several members of the Forth Standards Team.

## Annex C (informative) Compatibility analysis

Before this standard, there were several industry standards for Forth. The most influential are listed here in chronological order, along with the major differences between this standard and the most recent, Forth 94.

### C.1 FIG Forth (circa 1978)

FIG Forth was a “model” implementation of the Forth language developed by the Forth Interest Group (FIG). In FIG Forth, a relatively small number of words were implemented in processor-dependent machine language and the rest of the words were implemented in Forth. The FIG model was placed in the public domain, and was ported to a wide variety of computer systems. Because the bulk of the FIG Forth implementation was the same across all machines, programs written in FIG Forth enjoyed a substantial degree of portability, even for “system-level” programs that directly manipulate the internals of the Forth system implementation.

FIG Forth implementations were influential in increasing the number of people interested in using Forth. Many people associate the implementation techniques embodied in the FIG Forth model with “the nature of Forth”.

However, FIG Forth was not necessarily representative of commercial Forth implementations of the same era. Some of the most successful commercial Forth systems used implementation techniques different from the FIG Forth “model”.

### C.2 Forth 79

The Forth-79 Standard resulted from a series of meetings from 1978 to 1980, by the Forth Standards Team, an international group of Forth users and vendors (interim versions known as Forth 77 and Forth 78 were also released by the group).

Forth 79 described a set of words defined on a 16-bit, twos-complement, unaligned, linear byte-addressing virtual machine. It prescribed an implementation technique known as “indirect threaded code”, and used the ASCII character set.

The Forth-79 Standard served as the basis for several public domain and commercial implementations, some of which are still available and supported today.

### C.3 Forth 83

The Forth-83 Standard, also by the Forth Standards Team, was released in 1983. Forth 83 attempted to fix some of the deficiencies of Forth 79.

Forth 83 was similar to Forth 79 in most respects. However, Forth 83 changed the definition of several well-defined features of Forth 79. For example, the rounding behavior of integer division, the base value of the operands of **PICK** and **ROLL**, the meaning of the address returned by **'**, the compilation behavior of **'**, the value of a “true” flag, the meaning of **NOT**, and the “chaining” behavior of words defined by **VOCABULARY** were all changed. Forth 83 relaxed the implementation restrictions of Forth 79 to allow

any kind of threaded code, but it did not fully allow compilation to native machine code (this was not specifically prohibited, but rather was an indirect consequence of another provision).

Many new Forth implementations were based on the Forth-83 Standard, but few “strictly compliant” Forth-83 implementations exist.

Although the incompatibilities resulting from the changes between Forth 79 and Forth 83 were usually relatively easy to fix, a number of successful Forth vendors did not convert their implementations to be Forth 83 compliant. For example, the most successful commercial Forth for Apple Macintosh computers is based on Forth 79.

## C.4 ANS Forth (1994)

In the mid to late 1980s the computer industry underwent a rapid and profound change. The personal-computer market matured into a business and commercial market, while the market for ROM-based embedded control computers grew substantially. Improvements in custom processor design allowed for the development of numerous “Forth chips,” customized for the execution of the Forth language.

In order to take full advantage of evolving technology, many Forth implementations ignored some of the restrictions imposed by the implied “virtual machine” of previous standards. The ANS Forth committee was formed in 1987 to address the fragmentation within the Forth community caused not only by the difference between Forth 79 and Forth 83 but the exploitation of technical developments.

The committee undertook a comprehensive review of a variety of existing implementations, especially those with substantial user bases and/or considerable success in the market place. This allowed them to identify and document features common to these systems, many of which had not been included in any previous standard. This was the most comprehensive review of Forth systems to date, taking eighty-seven days covering twenty-three meetings over eight years. The inclusive nature of the standard allowed the various factions within the community to unify in support of ANS Forth, with many systems providing a compatibility layer.

The committee chose to move away from prescribing stringent requirements as previous standards had, with the specification of a virtual machine. It preferred to describe the operation of the virtual machine, without reference to its implementation, thus allowing an implementor to take full advantage of any technical developments while providing the developer with a complete list of entitlements.

This required the identification of implicit assumptions made by the previous standards, making them explicit and abstracting them into more general concepts where possible. A good example of this is the size of an item on the stack. In previous standards this was assumed to be 16 bits wide. This was no longer a valid assumption. ANS Forth introduced the concept of the *cell*, allowing an implementation to use a stack size most suited to the environment.

The American National Standards Institution (ANSI) published the ANS Forth Standard in 1994 with the title “ANSI X3.215-1994 Information Systems — Programming Language FORTH”. This is referenced throughout this document as Forth 94.

## C.5 ISO Forth (1997)

ANSI submitted the Forth 94 Standard to the ISO (International Organization for Standardization) and IEC (International Electrotechnical Commission) joint committee for consideration as an international standard.

The ISO/IEC adopted the Forth 94 document as an international standard in 1997, publishing it under the title “*ISO/IEC 15145:1997 Information technology. Programming languages. FORTH*”.

## C.6 Approach of this standard

During a workshop on the Forth standard at the EuroForth conference in 2004 it was agreed that Forth 94 required updating.

A committee was formed and agreed that the process should be as open as possible, adopting the Usenet RfD/CfV (Request for Discussion/Call for Votes) process to produce semi-formal proposals for changes to the standard. In addition to general discussion on the `comp.lang.forth` usenet news group, a moderated mailing list (with public archive) was created for those who do not follow the news group. Standards meetings to discuss CfVs were held in public in conjunction with the EuroForth conference.

The work of the Forth 94 committee was the basis of this standard, informally called Forth 200x. The aim of the Forth 200x committee is to produce a rolling document, with the standard constantly being updated based on discussion of proposals and the corresponding votes. A snapshot document is occasionally produced, with this document being the first.

The Forth 200x committee defined a procedure for proposals. In addition to the formal text of the proposal, they had to include: the rationale behind the change; a reference implementation, or a description of the reason a reference implementation cannot be presented; unit testing for the proposed change, especially for border conditions. See [Proposals Process](#) (page [viii](#)) for a full description.

## C.7 Differences from Forth 94

### C.7.1 Removed Obsolete Words

Forth 94 declared seven words as ‘obsolescent’, all but **FORGET** have been removed from this standard.

**Words affected:**

#TIB, CONVERT, EXPECT, QUERY, SPAN, TIB, **WORD**.

**Reason:**

Obsolescent words have been removed.

**Impact:**

**WORD** is no longer required to leave a space at the end of the returned string.

It is recommended that, should the obsolete words be included, they have the behaviour described in Forth 94. The names should not be reused for other purposes.

**Transition/Conversion:**

The functions of TIB and #TIB have been superseded by **SOURCE**.

The function of CONVERT has been superseded by **>NUMBER**.

The functions of EXPECT and SPAN have been superseded by **ACCEPT**.

The function of QUERY may be performed with **ACCEPT** and **EVALUATE**.

### C.7.2 Separate Floating-point Stack is now Standard

Previously systems could implement either a separate floating-point stack or a combined floating-point/data stack; programs were required to cater for both (or declare an environmental dependency on a particular variant).

**Words Affected:**

All floating-point words.

**Reason:**

The developing of software that may be used with either a combined stack or a separate stack is extremely difficult and costly. While some of the systems surveyed provide a combined floating-point/data stack, they all provide a separate floating-point stack.

**Impact:**

Forth 94 programs with an environmental dependency on a separate floating-point stack become standard programs.

Forth 94 programs with an environmental dependency on a combined stack retain the environmental dependency.

Forth 94 programs (without environmental dependency, i.e., those working on either kind of system) remain standard programs.

Forth 94 systems that implement a separate floating-point stack continue to be standard systems.

Forth 94 systems that implement a combined stack become systems with an environmental restriction of not providing a separate floating-point stack, but a combined stack.

**Transition/Conversion:**

Any code that has an environmental dependency on the use of a combined floating-point/data stack should be ported to use a separate floating-point stack.

A system that has an environmental restriction on using a combined floating-point/data stack should consider providing a separate floating-point stack.

### C.7.3 Using **ENVIRONMENT?** to inquire whether a word set is present

With the advent of a new standard, it was necessary to review the meaning of word set queries. Compatibility with Forth 94 demands that a word set query produce the same result as for Forth 94; i.e., querying for `CORE-EXT` returns true only if all the Forth 94 `CORE EXT` words are present. The question was how to distinguish between word sets described by this and subsequent standards.

The committee considered adding a year indicator to the word set name (“`CORE-EXT-2012`”) or a providing a general query (“`Forth-2012`”) which could be combined with the word-set query. As the committee could find very few examples of the word-set queries being used, it chose not to update the word set-query mechanism, but rather to mark it as obsolescent.

**Words Affected:**

**ENVIRONMENT?**

**Reason:**

The use of the word-set query to inquire whether a word set is present in the system has been marked obsolescent. If present the query indicates the word set, as documented in Forth 94, is available.

**Impact:**

Forth 94 did not guarantee the presence of these queries. Many systems that provided all the words in a particular word set did not provide the corresponding query. Portable programs are not affected as they could not rely on this function.

**Transition/Conversion:**

There is no direct equivalent to determine the presence of a whole word set. The [15.6.2.2530.30 \[DEFINED\]](#) and [15.6.2.2534 \[UNDEFINED\]](#) words can be used to detect the availability (or otherwise) of individual words.

**C.7.4 Additional TO targets**

[6.2.2295](#) TO has been extended to act on targets defined with [12.6.2.1628](#) FVALUE and [8.6.2.0435](#) 2VALUE.

**Words affected:**

TO

**C.7.5 Input/Output return values****Words affected:**

All words that return an *ior*.

**Reason:**

Forth 94 left the error code (*ior*) implementation-defined, although it did recommend an *ior* to be a [THROW](#) code. Forth 2012 now requires an *ior* to be a [THROW](#) code.

**Transition/Conversion:**

Forth 94 programs are not affected. Programs that are dependent on *iors* being throwable are no longer required to document the dependency.

Forth 94 systems that abided by the recommendation are not affected. Systems that did not heed this advice are required to do so. A number of [THROW](#) codes were added to table [9.1](#) to ease this transition.

**C.7.6 Minimum number of locals****Words affected:**

[\(LOCAL\)](#), [LOCALS |](#)

**Reason:**

Some programs require more than eight locals.

**Transition/Conversion:**

Existing programs are unaffected. Systems implementing the locals word set have to be changed to support at least 16 (previously 8) locals.

### C.7.7 Number prefixes

Decimal, hexadecimal, binary number literals can now be written irrespective of **BASE** by using the prefix #, \$, %. Also, character literals can be written as 'c'.

Standard programs are unaffected. Systems have to be changed to recognize these forms.

See [3.4.1.3 Text interpreter input number conversion](#).

### C.7.8 SOURCE-ID Clarification

When interpreting text from a file, the relationship between the position in the file returned by **SOURCE-ID**, and the current interpretation position is undefined.

### C.7.9 FASINH

An ambiguous condition on *rI* being less than 0 was removed.

Existing programs are not affected. Existing systems are unlikely to be affected.

### C.7.10 FATAN2

#### Words affected:

**FATAN2**

#### Reason:

The result is now specified more tightly: it is the principal angle (between -pi and pi).

#### Impact:

Forth 94 compliant programs are not affected.

#### Transition/Conversion:

Systems may have to change **FATAN2** to return the principal angle.

## C.8 Additional words

The following words have been added to the standard:

### C.8.6 Core word sets

The following words have been added to [6.2 Core extension words](#):

<a href="#">6.2.0698</a> ACTION-OF	<a href="#">6.2.1175</a> DEFER!	<a href="#">6.2.1725</a> IS
<a href="#">6.2.0825</a> BUFFER:	<a href="#">6.2.1177</a> DEFER@	<a href="#">6.2.2020</a> PARSE-NAME
<a href="#">6.2.1173</a> DEFER	<a href="#">6.2.1675</a> HOLDS	<a href="#">6.2.2266</a> S \ "

### C.8.8 Double-Number word sets

The following words have been added to [8.6.2 Double-Number extension words](#):

[8.6.2.0435](#) 2VALUE

### C.8.10 Facility word sets

The following words have been added to [10.6.2 Facility extension words](#):

<a href="#">10.6.2.0135</a> +FIELD	<a href="#">10.6.2.1740.06</a> K-F1	<a href="#">10.6.2.1740.17</a> K-F9
<a href="#">10.6.2.0763</a> BEGIN-STRUCTURE	<a href="#">10.6.2.1740.07</a> K-F10	<a href="#">10.6.2.1740.18</a> K-HOME
<a href="#">10.6.2.0893</a> CFIELD :	<a href="#">10.6.2.1740.08</a> K-F11	<a href="#">10.6.2.1740.19</a> K-INSERT

### C.8.18 Extended-Character word sets

The Extended Character word set was introduced by Forth-2012.

The following words make up **18 The optional Extended-Character word set**:

<b>18.6.1.2486.50</b> X-SIZE	<b>18.6.1.2487.25</b> XC-SIZE	<b>18.6.1.2488.30</b> XKEY
<b>18.6.1.2487.10</b> XC!+	<b>18.6.1.2487.35</b> XC@+	<b>18.6.1.2488.35</b> XKEY?
<b>18.6.1.2487.15</b> XC!+?	<b>18.6.1.2487.40</b> XCHAR+	<b>18.6.2.0145</b> +X/STRING
<b>18.6.1.2487.20</b> XC,	<b>18.6.1.2488.10</b> XEMIT	<b>18.6.2.0175</b> -TRAILING-GARBAGE

The following words make up **18.6.2 Extended-Character extension words**:

<b>18.6.2.0895</b> CHAR	<b>18.6.2.2486.70</b> X-WIDTH	<b>18.6.2.2488.20</b> XHOLD
<b>18.6.2.1306.60</b> EKEY>XCHAR	<b>18.6.2.2487.30</b> XC-WIDTH	<b>18.6.2.2495</b> X\STRING-
<b>18.6.2.2008</b> PARSE	<b>18.6.2.2487.45</b> XCHAR-	<b>18.6.2.2520</b> [CHAR]

## Annex D

(informative)

### Portability guide

#### D.1 Introduction

A primary goal of Forth 94 was to enable a programmer to write Forth programs that work on a wide variety of machines, Forth-2012 continues this practice. This goal is accomplished by allowing some key Forth terms to be implementation defined (e.g., cell size) and by providing Forth operators (words) that conceal the implementation. This allows the implementor to produce the Forth system that most effectively uses the native hardware. The machine independent operators, together with some programmer discipline, support program portability.

It can be difficult for someone familiar with only one machine architecture to imagine the problems caused by transporting programs between dissimilar machines. This Annex provides guidelines for writing portable Forth programs. The first section describes ways to make a program hardware independent.

The second section describes assumptions about Forth implementations that many programmers make, but can't be relied upon in a portable program.

#### D.2 Hardware peculiarities

##### D.2.1 Data/memory abstraction

This standard gives definitions for data and memory that apply to a wide variety of computers. These definitions give us a way to talk about the common elements of data and memory while ignoring the details of specific hardware. Similarly, Forth programs that use data and memory in ways that conform to these definitions can also ignore hardware details. The following sections discuss the definitions and describe how to write programs that are independent of the data and memory peculiarities of different computers.

##### D.2.2 Definitions

Three terms defined by this standard are address unit, cell, and character.

The address space of a Forth system is divided into an array of address units; an address unit is the smallest collection of bits that can be addressed. In other words, an address unit is the number of bits spanned by the addresses *addr* and *addr+1*. The most prevalent machines use 8-bit address units, but other address unit sizes exist.

In this standard, the size of a cell is an implementation-defined number of address units. Forth implemented on a 16-bit microprocessor could use a 16-bit cell and an implementation on a 32-bit machine could use a 32-bit cell. Less common cell sizes (e.g., 18-bit or 36-bit machines, etc.) could implement Forth systems with their native cell sizes. In all of these systems, Forth words such as **DUP** and **!** do the same things (duplicate the top cell on the stack and store the second cell into the address given by the first cell, respectively).

Similarly, the definition of a character has been generalized to be an implementation-defined number of address units (but at least eight bits). This removes the need for a Forth implementor to provide 8-bit characters on processors where it is inappropriate. For example, on an 18-bit machine with a 9-bit address

unit, a 9-bit character would be most convenient. Since, by definition, you can't address anything smaller than an address unit, a character must be at least as big as an address unit. This will result in big characters on machines with large address units. An example is a 16-bit cell addressed machine where a 16-bit character makes the most sense.

### D.2.3 Addressing memory

One of the most common portability problems is the addressing of successive cells in memory. Given the memory address of a cell, how do you find the address of the next cell? On a byte-addressed machine with 32-bit cells the code to find the next cell would be `4 +`. The code would be `1+` on a cell-addressed processor and `16 +` on a bit-addressed processor with 16-bit cells. This standard provides a next-cell operator named `CELL+` that can be used in all of these cases. Given an address, `CELL+` adjusts the address by the size of a cell (measured in address units).

A related problem is that of addressing an array of cells in an arbitrary order. This standard provides a portable scaling operator named `CELLS`. Given a number  $n$ , `CELLS` returns the number of address units needed to hold  $n$  cells. Using `CELLS`, we can make a portable definition of an `ARRAY` defining word:

```
: ARRAY ( u -- ) CREATE CELLS ALLOT
  DOES> ( u -- addr ) SWAP CELLS + ;
```

There are also portability problems with addressing arrays of characters. In a byte-addressed machine, the size of a character equals the size of an address unit. Addresses of successive characters in memory can be found using `1+` and scaling indices into a character array is a no-op (i.e., `1 *`). However, there could be implementations where a character is larger than an address unit. The `CHAR+` and `CHARS` operators, analogous to `CELL+` and `CELLS` are available to allow maximum portability.

This standard generalizes the definition of some Forth words that operate on regions of memory to use address units. One example is `ALLOT`. By prefixing `ALLOT` with the appropriate scaling operator (`CELLS`, `CHARS`, etc.), space for any desired data structure can be allocated (see definition of array above). For example:

```
CREATE ABUFFER 5 CHARS ALLOT ( allot 5 character buffer)
```

### D.2.4 Alignment problems

Some processors have restrictions on the addresses that can be used by memory access instructions. This standard does not require an implementor of a Forth to make alignment transparent; on the contrary, it requires (in Section 3.3.3.1 [Address alignment](#)) that a standard Forth program assume that character and cell alignment may be required. One pitfall caused by alignment restrictions is in creating tables containing both characters and cells. When `,` (comma) or `C,` is used to initialize a table, data are stored at the data-space pointer. Consequently, it must be suitably aligned. For example, a non-portable table definition would be:

```
CREATE ATABLE 1 C, X , 2 C, Y ,
```

On a machine that restricts memory fetches to aligned addresses, `CREATE` would leave the data space pointer at an aligned address. However, the first `C,` would leave the data space pointer at an unaligned address, and the subsequent `,` (comma) would violate the alignment restriction by storing `X` at an unaligned address. A portable way to create the table is:

```
CREATE ATABLE 1 C, ALIGN X , 2 C, ALIGN Y ,
```

**ALIGN** adjusts the data space pointer to the first aligned address greater than or equal to its current address. An aligned address is suitable for storing or fetching characters, cells, cell pairs, or double-cell numbers. After initializing the table, we would also like to read values from the table. For example, assume we want to fetch the first cell, X, from the table. `ATABLE CHAR+` gives the address of the first thing after the character. However this may not be the address of X since we aligned the dictionary pointer between the `C,` and the `,`. The portable way to get the address of X is:

```
ATABLE CHAR+ ALIGNED
```

**ALIGNED** adjusts the address on top of the stack to the first aligned address greater than or equal to its current value.

## D.3 Number representation

### D.3.1 Big endian vs. little endian

The constituent bits of a number in memory are kept in different orders on different machines. Some machines place the most-significant part of a number at an address in memory with less-significant parts following it at higher addresses; this is known as big-endian ordering. Other machines do the opposite; the least-significant part is stored at the lowest address (little-endian ordering).

For example, the following code for a 16-bit little endian Forth would produce the answer 1:

```
VARIABLE FOO 1 FOO ! FOO C@
```

The same code on a 16-bit big-endian Forth would produce the answer 0. A portable program cannot exploit the representation of a number in memory.

A related issue is the representation of cell pairs and double-cell numbers in memory. When a cell pair is moved from the stack to memory with `2!`, the cell that was on top of the stack is placed at the lower memory address. It is useful and reasonable to manipulate the individual cells when they are in memory.

#### **Editor:**

*This would be a good place to add a discussion of characters and the extended character word set.*

## D.4 Forth system implementation

During Forth's history, an amazing variety of implementation techniques have been developed. The ANS Forth Standard encourages this diversity and consequently restricts the assumptions a user can make about the underlying implementation of an ANS Forth system. Users of a particular Forth implementation frequently become accustomed to aspects of the implementation and assume they are common to all Forths. This section points out many of these incorrect assumptions.

### D.4.1 Definitions

Traditionally, Forth definitions have consisted of the name of the Forth word, a dictionary search link, data describing how to execute the definition, and parameters describing the definition itself. These components have historically been referred to as the name, link, code, and parameter fields. No method for accessing these fields has been found that works across all of the Forth implementations currently in use. Therefore,

a portable Forth program may not use the name, link, or code field in any way. Use of the parameter field (renamed to data field for clarity) is limited to the operations described below.

Only words defined with **CREATE** or with other defining words that call **CREATE** have data fields. The other defining words in the standard (**VARIABLE**, **CONSTANT**, **:**, etc.) might not be implemented with **CREATE**. Consequently, a Standard Program must assume that words defined by **VARIABLE**, **CONSTANT**, **:**, etc., may have no data fields. There is no portable way for a Standard Program to modify the value of a constant or to “patch” a colon definition at run time. The **DOES>** part of a defining word operates on a data field, so **DOES>** may only be used on words ultimately defined by **CREATE**.

In standard Forth, **FIND**, **[ ' ]** and **'** (tick) return an unspecified entity called an execution token. There are only a few things that may be done with an execution token. The token may be passed to **EXECUTE** to execute the word ticked or compiled into the current definition with **COMPILE,** . The token can also be stored in a variable or other data structure and used later. Finally, if the word ticked was defined via **CREATE**, **>BODY** converts the execution token into the word’s data-field address.

An execution token cannot be assumed to be an address and may not be used as one.

## D.4.2 Stacks

In some Forth implementations, it is possible to find the address of a stack in memory and manipulate the stack as an array of cells. This technique is not portable. On some systems, especially Forth-in-hardware systems, the stacks might be in memory that can’t be addressed by the program or might not be in memory at all. Forth’s parameter and return stacks must be treated as stacks.

A Standard Program may use the return stack directly only for temporarily storing values. Every value examined or removed from the return stack using **R@**, **R>**, or **2R>** must have been put on the stack explicitly using **>R** or **2>R**. Even this must be done carefully because the system may use the return stack to hold return addresses and loop-control parameters. Section **3.2.3.3 Return stack** of the standard has a list of restrictions.

## D.5 Summary

The Forth Standard does not force anyone to write a portable program. In situations where performance is paramount, the programmer is encouraged to use every trick available. On the other hand, if portability to a wide variety of systems is needed (or anticipated), this standard provides the tools to accomplish this. There might be no such thing as a completely portable program. A programmer, using this guide, should intelligently weigh the tradeoffs of providing portability to specific machines. For example, machines that use sign-magnitude numbers are rare and probably don’t deserve much thought. But, systems with different cell sizes will certainly be encountered and should be provided for. In general, making a program portable clarifies both the programmer’s thinking process and the final program.

## Annex E (informative) Reference Implementations

### E.1 Introduction

In the most recent review of this document, proposals were encouraged to include a reference implementation where possible. Where an implementation requires system specific knowledge it was documented.

This appendix contains the reference implementations that have been accepted by the committee. This is not a complete reference implementation nor do the committee recommend these implementations. They are supplied solely for the purpose of providing a detailed understanding of a definitions requirement. System implementors are free to implement any operation in a manner that suits their system, but it must exhibit the same behavior as the reference implementation given here.

### E.6 The Core word set

#### E.6.1.1910 **NEGATE**

x:2-complement

```

: ( n1 -- n2 )
  NEGATE INVERT 1+
;

```

#### E.6.1.2050 **QUIT**

```

: QUIT
  ( empty the return stack and set the input source to the user input device )
  POSTPONE [
    REFILL
  WHILE
    [ ' ] INTERPRET CATCH
  CASE
    0 OF STATE @ 0= IF ." OK" THEN CR ENDOF
    -1 OF ( Aborted ) ENDOF
    -2 OF ( display message from ABORT" ) ENDOF
    ( default ) DUP ." Exception # " .
  ENDCASE
  REPEAT BYE
;

```

This assumes the existence of a system-implementation word `INTERPRET` that embodies the text interpreter semantics described in [3.4 The Forth text interpreter](#). Further discussion of the interpret loop can be found in [A.6.2.0945 `COMPILE,`](#).

#### E.6.2.0698 **ACTION-OF**

```

: ACTION-OF
  STATE @ IF
    POSTPONE [ ' ] POSTPONE DEFER@
  ELSE

```

```

    ' DEFER@
    THEN ; IMMEDIATE

```

**E.6.2.0825 BUFFER:**

This implementation depends on children of **CREATE** returning an aligned address. Other memory location techniques require implementation-specific knowledge of the underlying Forth system.

```

: BUFFER: \ u "<name>" -- ; -- addr
\ Create a buffer of u address units whose address is returned at run time.
CREATE ALLOT
;

```

**E.6.2.1173 DEFER**

```

: DEFER ( "name" -- )
  CREATE ['] ABORT ,
DOES> ( ... -- ... )
  @ EXECUTE ;

```

**E.6.2.1175 DEFER!**

```

: DEFER! ( xt2 xt1 -- )
  >BODY ! ;

```

**E.6.2.1177 DEFER@**

```

: DEFER@ ( xt1 -- xt2 )
  >BODY @ ;

```

**E.6.2.1675 HOLDS**

```

: HOLDS ( addr u -- )
  BEGIN DUP WHILE 1- 2DUP + C@ HOLD REPEAT 2DROP ;

```

**E.6.2.1725 IS**

```

: IS
  STATE @ IF
    POSTPONE ['] POSTPONE DEFER!
  ELSE
    ' DEFER!
  THEN ; IMMEDIATE

```

**E.6.2.2020 PARSE-NAME**

```

: isspace? ( c -- f )
  BL 1+ U< ;

: isnotspace? ( c -- f )
  isspace? 0= ;

: xt-skip ( addr1 n1 xt -- addr2 n2 )
  \ skip all characters satisfying xt ( c -- f )
  >R
  BEGIN
    DUP

```

```

WHILE
  OVER C@ R@ EXECUTE
WHILE
  1 /STRING
REPEAT THEN
R> DROP ;

: parse-name ( "name" -- c-addr u )
SOURCE >IN @ /STRING
['] isspace? xt-skip OVER >R
['] isnotspace? xt-skip ( end-word restlen r: start-word )
2DUP 1 MIN + SOURCE DROP - >IN !
DROP R> TUCK - ;

```

**E.6.2.2440 WITHIN**

```

: WITHIN ( test low high -- flag )
OVER - >R - R> U<
;

```

**E.8 The optional Double-Number word set****E.8.6.1.1140 D>S**

```

: S>D D>S ( d -- n )
DROP
;

```

x:2-complement

**E.8.6.2.0435 2VALUE**

The implementation of **TO** to include **2VALUES** requires detailed knowledge of the host implementation of **VALUE** and **TO**, which is the main reason why **2VALUE** should be standardized. The order in which the two cells are stored in memory is not specified in the definition for **2VALUE** but this reference implementation has to assume one ordering — this is not intended to be definitive.

```

: 2VALUE ( x1 x2 -- )
CREATE , ,
DOES> 2@ ( -- x1 x2 )
;

```

The corresponding implementation of **TO** disregards the issue that **TO** must also work for integer **VALUES** and locals.

```

: TO ( x1 x2 "<spaces>name" -- )
' >BODY
STATE @ IF
  POSTPONE 2LITERAL POSTPONE 2!
ELSE
  2!

```

```

    THEN
  ; IMMEDIATE

```

## E.9 The optional Exception word set

### E.9.6.1.0875 CATCH

This sample implementation of **CATCH** uses the non-standard words described below. They or their equivalents are available in many systems. Other implementation strategies, including directly saving the value of **DEPTH**, are possible if such words are not available.

**SP@** ( -- *addr* )  
returns the address corresponding to the top of data stack.

**SP!** ( *addr* -- )  
sets the stack pointer to *addr*, thus restoring the stack depth to the same depth that existed just before *addr* was acquired by executing **SP@**.

**RP@** ( -- *addr* )  
returns the address corresponding to the top of return stack.

**RP!** ( *addr* -- )  
sets the return stack pointer to *addr*, thus restoring the return stack depth to the same depth that existed just before *addr* was acquired by executing **RP@**.

**VARIABLE** HANDLER 0 HANDLER ! \ last exception handler

```

: CATCH ( xt -- exception# | 0 \ return addr on stack
  SP@ >R ( xt ) \ save data stack pointer
  HANDLER @ >R ( xt ) \ and previous handler
  RP@ HANDLER ! ( xt ) \ set current handler
  EXECUTE ( ) \ execute returns if no THROW
  R> HANDLER ! ( ) \ restore previous handler
  R> DROP ( ) \ discard saved stack ptr
  0 ( 0 ) \ normal completion
;

```

In a multi-tasking system, the **HANDLER** variable should be in the per-task variable area (i.e., a user variable).

This sample implementation does not explicitly handle the case in which **CATCH** has never been called (i.e., the **ABORT** behavior). One solution would be to execute a **CATCH** within **QUIT**, so that there is always an “exception handler of last resort” present, as shown in [E.6.1.2050 QUIT](#).

### E.9.6.1.2275 THROW

This is the counter part to [E.9.6.1.0875 CATCH](#).

```

: THROW ( ??? exception# -- ??? exception# )
  ?DUP IF ( exc# ) \ 0 THROW is no-op
  HANDLER @ RP! ( exc# ) \ restore prev return stack
  R> HANDLER ! ( exc# ) \ restore prev handler
  R> SWAP >R ( saved-sp ) \ exc# on return stack

```

```

    SP! DROP R> ( exc# ) \ restore stack
    \ Return to the caller of CATCH because return
    \ stack is restored to the state that existed
    \ when CATCH began execution
    THEN
  ;

```

**E.9.6.2.0670 ABORT**

```

: ABORT -1 THROW ;

```

**E.10 The optional Facility word set****E.10.6.2.0135 +FIELD**

Create a new field within a structure definition of size *n* bytes.

```

: +FIELD \ n <"name"> -- ; Exec: addr -- 'addr
  CREATE OVER , +
  DOES> @ +
;

```

**E.10.6.2.0763 BEGIN-STRUCTURE**

Begin definition of a new structure. Use in the form **BEGIN-STRUCTURE** *<name>*. At run time *<name>* returns the size of the structure.

```

: BEGIN-STRUCTURE \ -- addr 0 ; -- size
  CREATE
    HERE 0 0 , \ mark stack, lay dummy
  DOES> @ \ -- rec-len
;

```

**E.10.6.2.1306.40 EKEY>FKEY**

The implementation is closely tied to the implementation of **EKEY** and therefore unportable.

**E.10.6.2.1336 END-STRUCTURE**

Terminate definition of a structure.

```

: END-STRUCTURE \ addr n --
  SWAP ! ; \ set len

```

**E.11 The optional File-Access word set****E.11.6.2.1714 INCLUDE**

```

: INCLUDE ( i*x "name" -- j*x )
  PARSE-NAME INCLUDED ;

```

**E.11.6.2.2144.10 REQUIRE**

```

: REQUIRE ( i*x "name" -- i*x )
  PARSE-NAME REQUIRED ;

```

**E.11.6.2.2144.50 REQUIRED**

This implementation does not implement the requirements with regard to **MARKER** and **FORGET** (**REQUIRED** only includes each file once, whether a marker was executed or not), so it is not a correct implementation on systems that support these words. It extends the definition of **INCLUDED** to record the name of files which have been either included or required previously. The names are recorded in a linked list held in the `included-names` variable.

```

: save-mem ( addr1 u -- addr2 u ) \ gforth
\ copy a memory block into a newly allocated region in the heap
  SWAP >R
  DUP ALLOCATE THROW
  SWAP 2DUP R> ROT ROT MOVE ;

## Annex F (informative) Test Suite

### F.1 Introduction

After the publication of the original ANS Forth document (ANSI X3.215-1994), John Hayes developed a test suite, which included both a test harness and a suite of core tests. The harness was extended by Anton Ertl and David N. Williams to allow the testing of floating point operations. The current revision of the test harness is available from the web site:

<http://www.forth200x.org/tests/ttester.fs>

The test harness can be used to define regression tests for a set of application words. It can also be used to define tests of words in a standard-conforming implementation.

Numerous people have contributed to the test cases given in section F.3 onwards. The majority of the test cases have been taken from John Hayes' test suite<sup>1</sup>, Gerry Jackson's test suite<sup>2</sup> and David Williams with significant contributions from the committee.

### F.2 Test Harness

The tester defines functions that compare the results of a test with a set of expected results. The syntax for each test starts with “T{” (T-open brace) followed by a code sequence to test. This is followed by “->”, the expected results, and “}T” (close brace-T). For example, the following:

```
T{ 1 1 + -> 2 }T
```

tests that one plus one indeed equals two.

The “T{” records the stack depth prior to the test code so that they can be eliminated from the test. The “->” records the stack depth and moves the entire stack contents to an array. In the example test, the recorded stack depth is one and the saved array contains one value, two. The “}T” compares the current stack depth to the saved stack depth. If they are equal each value on the stack is removed from the stack and compared to its corresponding value in the array. If the depths are not equal or if the stack comparison fails, an error is reported. For example:

```
T{ 1 2 3 SWAP -> 1 3 2 }T
T{ 1 2 3 SWAP -> 1 2 3 }T INCORRECT RESULT: T{ 1 2 3 SWAP -> 1 2 3 }T
T{ 1 2 SWAP -> 1 }T WRONG NUMBER OF RESULTS: T{ 1 2 SWAP -> 1 }T
```

#### F.2.1 Floating-Point

Floating point testing can involve further complications. The harness attempts to determine whether floating-point support is present, and if so, whether there is a separate floating-point stack, and behave

<sup>1</sup><http://www.taygeta.com/forth.html>

<sup>2</sup><http://soton.mpeforth.com/flag/anstests/index.html>

accordingly. The **CONSTANT**s `HAS-FLOATING` and `HAS-FLOATING-STACK` contain the results of its efforts, so the behavior of the code can be modified by the user if necessary.

Then there are the perennial issues of floating point value comparisons. Exact equality is specified by `SET-EXACT` (the default). If approximate equality tests are desired, execute `SET-NEAR`. Then the **FVARIABLE**s `REL-NEAR` (default 1E-12) and `ABS-NEAR` (default 0E) contain the values to be used in comparisons by the (internal) word `FNEARLY=`.

When there is not a separate floating point stack, and you want to use approximate equality for FP values, it is necessary to identify which stack items are floating point quantities. This can be done by replacing the closing `}T` with a version that specifies this, such as `RRXR}T` which identifies the stack picture (*r r x r*). The harness provides such words for all combinations of R and X with up to four stack items. They can be used with either an integrated or a separate floating point stacks. Adding more if you need them is straightforward; see the examples in the source. Here is an example which also illustrates controlling the precision of comparisons:

```
SET-NEAR
1E-6 REL-NEAR F!
T{ S" 3.14159E" >FLOAT -> -1E FACOS <TRUE> RX}T
```

## F.2.2 Error Processing

The internal word `ERROR` is vectored, through the `ERROR-XT` variable, so that its action can be changed by the user (for example, to add a counter for the number of errors). The default action `ERROR1` can be used as a factor in the display of error reports.

## F.2.3 Source

The following source code provides the test harness.

```

## F.3 Core Tests

The test cases in John Hayes' original test suite were designed to test features before they were used in later tests. Due to the structure of this annex the progressive testing has been lost. This section attempts to retain the integrity of the original test suite by laying out the test progression for the core word set.

While this suite does test many aspects of the core word set, it is not comprehensive. A standard system *should* pass all of the tests within this suite. A system cannot claim to be standard simply because it passes this test suite.

The test starts by verifying basic assumptions about number representation. It then builds on this with tests of boolean logic, shifting, and comparisons. It then tests the basic stack manipulations and arithmetic. Ultimately, it tests the Forth interpreter and compiler.

Note that all of the tests in this suite assume the current base is *hexadecimal*.

### F.3.1 Basic Assumptions

These test assume a two's complement implementation where the range of signed numbers is  $-2^{n-1} \dots 2^{n-1} - 1$  and the range of unsigned numbers is  $0 \dots 2^n - 1$ .

A method for testing **KEY**, **QUIT**, **ABORT**, **ABORT"**, **ENVIRONMENT?**, etc has yet to be proposed.

```
T{  ->  }T          ( Start with a clean slate )
( Test if any bits are set; Answer in base 1 )
T{  : BITSSET? IF 0 0 ELSE 0 THEN ; ->  }T
T{  0 BITSSET? -> 0 }T    ( Zero is all bits clear )
T{  1 BITSSET? -> 0 0 }T  ( Other numbers have at least one bit )
T{ -1 BITSSET? -> 0 0 }T
```

### F.3.2 Booleans

To test the booleans it is first necessary to test **F.6.1.0720 AND**, and **F.6.1.1720 INVERT**. Before moving on to the test **F.6.1.0950 CONSTANT**. The latter defines two constants (0S and 1S) which will be used in the further test.

It is now possible to complete the testing of **F.6.1.0720 AND**, **F.6.1.1980 OR**, and **F.6.1.2490 XOR**.

### F.3.3 Shifts

To test the shift operators it is necessary to calculate the most significant bit of a cell:

```
1S 1 RSHIFT INVERT CONSTANT MSB
```

**RSHIFT** is tested later. MSB must have at least one bit set:

```
T{ MSB BITSSET? -> 0 0 }T
```

The test **F.6.1.0320 2\***, **F.6.1.0330 2/**, **F.6.1.1805 LSHIFT**, and **F.6.1.2162 RSHIFT** can now be performed.

### F.3.4 Numeric notation

The numeric representation can be tested with the following test cases:

#### DECIMAL

```
T{ #1289      -> 1289      }T
T{ #12346789. -> 12346789. }T
T{ #-1289     -> -1289     }T
T{ #-12346789. -> -12346789. }T
T{ $12eF      -> 4847      }T
T{ $12aBcDeF. -> 313249263. }T
T{ $-12eF     -> -4847     }T
T{ $-12AbCdeF. -> -313249263. }T
T{ %10010110  -> 150       }T
T{ %10010110. -> 150.         }T
T{ %-10010110 -> -150        }T
T{ %-10010110. -> -150.        }T
T{ ' z '      -> 122      }T
```

### F.3.5 Comparisons

Before testing the comparison operators it is necessary to define a few constants to allow the testing of the upper and lower bounds.

```
0 INVERT          CONSTANT MAX-UINT
0 INVERT 1 RSHIFT CONSTANT MAX-INT
0 INVERT 1 RSHIFT INVERT CONSTANT MIN-INT
0 INVERT 1 RSHIFT          CONSTANT MID-UINT
0 INVERT 1 RSHIFT INVERT CONSTANT MID-UINT+1

0S CONSTANT <FALSE>
1S CONSTANT <TRUE>
```

With these constants defined, it is now possible to perform the [F.6.1.0270](#) 0=, [F.6.1.0530](#) =, [F.6.1.0250](#) 0<, [F.6.1.0480](#) <, [F.6.1.0540](#) >, [F.6.1.2340](#) U<, [F.6.1.1880](#) MIN, and [F.6.1.1870](#) MAX test.

### F.3.6 Stack Operators

The stack operators can be tested without any preparatory work. The “normal” operators ([F.6.1.1260](#) DROP, [F.6.1.1290](#) DUP, [F.6.1.1990](#) OVER, [F.6.1.2160](#) ROT, and [F.6.1.2260](#) SWAP) should be tested first, followed by the two-cell variants ([F.6.1.0370](#) 2DROP, [F.6.1.0380](#) 2DUP, [F.6.1.0400](#) 2OVER and [F.6.1.0430](#) 2SWAP) with [F.6.1.0630](#) ?DUP and [F.6.1.1200](#) DEPTH being performed last.

### F.3.7 Return Stack Operators

The test [F.6.1.0580](#) >R will test all three basic return stack operators (>R, R>, and R@).

### F.3.8 Addition and Subtraction

Basic addition and subtraction should be tested in the order: **F.6.1.0120** +, **F.6.1.0160** −, **F.6.1.0290** 1+, **F.6.1.0300** 1−, **F.6.1.0690** ABS and **F.6.1.1910** NEGATE.

### F.3.9 Multiplication

The multiplication operators should be tested in the order: **F.6.1.2170** S>D, **F.6.1.0090** \*, **F.6.1.1810** M\*, and **F.6.1.2360** UM\*.

### F.3.10 Division

Due to the complexity of the division operators they are tested separately from the multiplication operators. The basic division operators are tested first: **F.6.1.1561** FM/MOD, **F.6.1.2214** SM/REM, and **F.6.1.2370** UM/MOD.

As the standard allows a system to provide either floored or symmetric division, the remaining operators have to be tested depending on the system behaviour. Two words are defined that provide a form of conditional compilation.

```
: IFFLOORED [ -3 2 / -2 = INVERT ] LITERAL IF POSTPONE \ THEN ;
: IFSYM      [ -3 2 / -1 = INVERT ] LITERAL IF POSTPONE \ THEN ;
```

IFSYM will ignore the rest of the line when it is performed on a system with floored division and perform the line on a system with symmetric division. IFFLOORED is the direct inverse, ignoring the rest of the line on systems with symmetric division and processing it on systems with floored division.

The remaining division operators are tested by defining a version of the operator using words which have already been tested (**S>D**, **M\***, **FM/MOD** and **SM/REM**). The test definition handles the special case of differing signs. As the test definitions use the words which have just been tested, the tests must be performed in the order: **F.6.1.0240** /MOD, **F.6.1.0230** /, **F.6.1.1890** MOD, **F.6.1.0100** \*/ , and **F.6.1.0110** \*/MOD.

### F.3.11 Memory

As with the other sections, the tests for the memory access words build on previously tested words and thus require an order to the testing.

The first test (**F.6.1.0150** , (comma)) tests **HERE**, the single cell memory access words **@**, **!** and **CELL+** as well as the double cell access words **2@** and **2!**. The tests **F.6.1.0130** +! and **F.6.1.0890** CELLS should then be performed.

The test (**F.6.1.0860** C , ) also tests the single character memory words **C@**, **C!**, and **CHAR+**, leaving the test **F.6.1.0898** CHARS to be performed separately.

Finally, the memory access alignment test **F.6.1.0705** ALIGN includes a test of **ALIGNED**, leaving **F.6.1.0710** ALLOT as the final test in this group.

### F.3.12 Characters

Basic character handling: **F.6.1.0770** BL, **F.6.1.0895** CHAR, **F.6.1.2520** [CHAR], **F.6.1.2500** [ which also tests ], and **F.6.1.2165** S".

### F.3.13 Dictionary

The dictionary tests define a number of words as part of the test, these are included in the appropriate test: [F.6.1.0070](#) ' , [F.6.1.2510](#) [ ' ] both of which also test [EXECUTE](#), [F.6.1.1550](#) FIND, [F.6.1.1780](#) LITERAL, [F.6.1.0980](#) COUNT, [F.6.1.2033](#) POSTPONE, [F.6.1.2250](#) STATE

### F.3.14 Flow Control

The flow control words have to be tested in matching groups. First test [F.6.1.1700](#) IF, [ELSE](#), [THEN](#) group. Followed by the [BEGIN](#), [F.6.1.2430](#) WHILE, [REPEAT](#) group, and the [BEGIN](#), [F.6.1.2390](#) UNTIL pairing. Finally the [F.6.1.2120](#) RECURSE function should be tested.

### F.3.15 Counted Loops

Counted loops have a set of special condition that require testing. As with the flow control words, these words have to be tested as a group. First the basic counted loop: [DO](#); [I](#); [F.6.1.1800](#) LOOP, followed by loops with a non regular increment: [F.6.1.0140](#) +LOOP, loops within loops: [F.6.1.1730](#) J, and aborted loops: [F.6.1.1760](#) LEAVE; [F.6.1.2380](#) UNLOOP which includes a test for [EXIT](#).

### F.3.16 Defining Words

Although most of the defining words have already been used within the test suite, they still need to be tested fully. The tests include [F.6.1.0450](#) : which also tests [;](#), [F.6.1.0950](#) CONSTANT, [F.6.1.2410](#) VARIABLE, [F.6.1.1250](#) DOES> which includes tests [CREATE](#), and [F.6.1.0550](#) >BODY which also tests [CREATE](#).

### F.3.17 Evaluate

As with the defining words, [F.6.1.1360](#) EVALUATE has already been used, but it must still be tested fully.

### F.3.18 Parser Input Source Control

Testing of the input source can be quite difficult. The tests require line breaks within the test: [F.6.1.2216](#) SOURCE, [F.6.1.0560](#) >IN, and [F.6.1.2450](#) WORD.

### F.3.19 Number Patterns

The number formatting words produce a string, a word that compares two strings is required. This test suite assumes that the optional String word set is unavailable. Thus a string comparison word is defined, using only trusted words:

```
: S= \ ( ADDR1 C1 ADDR2 C2 -- T/F ) Compare two strings.
  >R SWAP R@ = IF          \ Make sure strings have same length
  R> ?DUP IF              \ If non-empty strings
    0 DO
      OVER C@ OVER C@ - IF 2DROP <FALSE> UNLOOP EXIT THEN
      SWAP CHAR+ SWAP CHAR+
    LOOP
  THEN
  2DROP <TRUE>            \ If we get here, strings match
ELSE
```

```

R> DROP 2DROP <FALSE> \ Lengths mismatch
THEN ;

```

The number formatting words have to be tested as a group with [F.6.1.1670 HOLD](#), [F.6.1.2210 SIGN](#), and [F.6.1.0030 #](#) all including tests for `<#` and `#>`.

Before the [F.6.1.0050 #S](#) test can be performed it is necessary to calculate the number of bits required to store the largest double value.

```

24 CONSTANT MAX-BASE          \ BASE 2 ... 36
: COUNT-BITS
  0 0 INVERT BEGIN DUP WHILE >R 1+ R> 2* REPEAT DROP ;
COUNT-BITS 2* CONSTANT #BITS-UD \ NUMBER OF BITS IN UD

```

The [F.6.1.0570 >NUMBER](#) test can now be performed. Finally, the [F.6.1.0750 BASE](#) test, which includes tests for `HEX` and `DECIMAL`, can be performed.

### F.3.20 Memory Movement

First two memory buffers are defined:

```

CREATE FBUF 00 C, 00 C, 00 C,
CREATE SBUF 12 C, 34 C, 56 C,
: SEEBUF FBUF C@ FBUF CHAR+ C@ FBUF CHAR+ CHAR+ C@ ;

```

As the content of FBUF is changed by the [F.6.1.1540 FILL](#) test, this must be executed before the [F.6.1.1900 MOVE](#) test.

### F.3.21 Output

As there is no provision for capturing the output stream so that it can be compared to an expected result there is not automatic method of testing the output generation words. The user is required to validate the output for the [F.6.1.1320 EMIT](#) test. This tests the selection of output words `..`, `."`, `CR`, `SPACE`, `SPACES`, `TYPE`, and `U..`

### F.3.22 Input

To test the input word ([F.6.1.0695 ACCEPT](#)) the user is required to type up to 80 characters. The system will buffer the input sequence and output it to the user for inspection.

### F.3.23 Dictionary Search Rules

The final test in this suite is included with [F.6.1.0450 :](#) and tests the search order of the dictionary. It asserts that a definition that uses its own name in the definition is not recursive but rather refers to the previous definition of the word.

```

T{ : GDX 123 ; -> }T \ First defintion
T{ : GDX GDX 234 ; -> }T \ Second defintion
T{ GDX -> 123 234 }T

```

```

With an immediate word

```
T{ : [c2] [COMPILE] [c1] ; -> }T
T{ 234 [c2] -> 234 234 }T
```

With special compilation semantics

```
T{ : [cif] [COMPILE] IF ; IMMEDIATE -> }T
T{ : [c3] [cif] 111 ELSE 222 THEN ; -> }T
T{ -1 [c3] -> 111 }T
T{ 0 [c3] -> 222 }T
```

## F.8 The optional Double-Number word set

Two additional constants are defined to assist tests in this word set:

```
MAX-INT 2/ CONSTANT HI-INT \ 001...1
MIN-INT 2/ CONSTANT LO-INT \ 110...1
```

Before anything can be tested, the text interpreter must be tested (F.8.3.2). Once the [F.8.6.1.0360 2CONSTANT](#) test has been performed we can also define a number of double constants:

```
1S MAX-INT 2CONSTANT MAX-2INT \ 01...1
0 MIN-INT 2CONSTANT MIN-2INT \ 10...0
MAX-2INT 2/ 2CONSTANT HI-2INT \ 001...1
MIN-2INT 2/ 2CONSTANT LO-2INT \ 110...0
```

The rest of the word set can be tested: [F.8.6.1.1230 DNEGATE](#), [F.8.6.1.1040 D+](#), [F.8.6.1.1050 D-](#), [F.8.6.1.1075 D0<](#), [F.8.6.1.1080 D0=](#), [F.8.6.1.1090 D2\\*](#), [F.8.6.1.1100 D2/](#), [F.8.6.1.1110 D<](#), [F.8.6.1.1120 D=](#), [F.8.6.1.0390 2LITERAL](#), [F.8.6.1.0440 2VARIABLE](#), [F.8.6.1.1210 DMAX](#), [F.8.6.1.1220 DMIN](#), [F.8.6.1.1140 D>S](#), [F.8.6.1.1160 DABS](#), [F.8.6.1.1830 M+](#), [F.8.6.1.1820 M\\*/](#) and [F.8.6.1.1070 D.R](#) which also tests [D.](#) before moving on to the existence words with the [F.8.6.2.0420 2ROT](#) and [F.8.6.2.1270 DU<](#) tests.

**F.9 The optional Exception word set**

The test [F.9.6.1.0875 CATCH](#) also test [THROW](#). This should be followed by the test [F.9.6.2.0680 ABORT](#) which also test [ABORT](#). Finally, the general exception handling is tested in [F.9.3.6](#).

**F.9.3.6 Exception handling**

Ideally all of the throw codes should be tested. Here only the throw code for an “Undefined Word” exception is tested, assuming that the word `$$UndefedWord$$` is undefined.

**DECIMAL**

```

: t7 S" 333 $$UndefedWord$$ 334" EVALUATE 335 ;
: t8 S" 222 t7 223" EVALUATE 224 ;
: t9 S" 111 112 t8 113" EVALUATE 114 ;

```

```
T{ 6 7 ' t9 c6 3 -> 6 7 13 3 }T
```

**F.9.6.1.0875 CATCH**

See [F.9.6.1.2275 THROW](#).

**F.9.6.1.2275 THROW****DECIMAL**

```

: t1 9 ;
: c1 1 2 3 ['] t1 CATCH ;
T{ c1 -> 1 2 3 9 0 }T \ No THROW executed

: t2 8 0 THROW ;
: c2 1 2 ['] t2 CATCH ;
T{ c2 -> 1 2 8 0 }T \ 0 THROW does nothing

: t3 7 8 9 99 THROW ;
: c3 1 2 ['] t3 CATCH ;
T{ c3 -> 1 2 99 }T \ Restores stack to CATCH depth

: t4 1- DUP 0> IF RECURSE ELSE 999 THROW -222 THEN ;
: c4 3 4 5 10 ['] t4 CATCH -111 ;
T{ c4 -> 3 4 5 0 999 -111 }T \ Test return stack unwinding

```

```

## F.11 The optional File-Access word set

These tests create files in the current directory, if all goes well these will be deleted. If something fails they may not be deleted. If this is a problem ensure you set a suitable directory before running this test. Currently, there is no ANS standard way of doing this. the file names used in these test are: “fatest1.txt”, “fatest2.txt” and “fatest3.txt”.

The test **F.11.6.1.1010 CREATE-FILE** also tests **CLOSE-FILE**, **F.11.6.1.2485 WRITE-LINE** also tests **W/O** and **OPEN-FILE**, **F.11.6.1.2090 READ-LINE** includes a test for **R/O**, **F.11.6.1.2142 REPOSITION-FILE** includes tests for **R/W**, **WRITE-FILE**, **READ-FILE**, **FILE-POSITION**, and **S**. The **F.11.6.1.1522 FILE-SIZE** test includes a test for **BIN**. The test **F.11.6.1.2147 RESIZE-FILE** should then be run followed by the **F.11.6.1.1190 DELETE-FILE** test.

The **F.11.6.1.0080 (** test should be next, followed by **F.11.6.1.2218 SOURCE-ID** the test which test the extended versions of **(** and **SOURCE-ID** respectively.

Finally **F.11.6.2.2130 RENAME-FILE** tests the extended words **RENAME-FILE**, **FILE-STATUS**, and **FLUSH-FILE**.

### F.11.6.1.0080 (

```

## F.14 The optional Memory-Allocation word set

These test require a new variable to hold the address of the allocated memory. Two helper words are defined to populate the allocated memory and to check the memory:

**VARIABLE** addr

```

: write-cell-mem ( addr n -- )
  1+ 1 DO I OVER ! CELL+ LOOP DROP
;

: check-cell-mem ( addr n -- )
  1+ 1 DO
    I SWAP >R >R
    T{ R> ( I ) -> R@ ( addr ) @ }T
    R> CELL+
  LOOP DROP
;

: write-char-mem ( addr n -- )
  1+ 1 DO I OVER C! CHAR+ LOOP DROP
;

: check-char-mem ( addr n -- )
  1+ 1 DO
    I SWAP >R >R
    T{ R> ( I ) -> R@ ( addr ) C@ }T
    R> CHAR+
  LOOP DROP
;

```

The test **F.14.6.1.0707 ALLOCATE** includes a test for **FREE**.

**F.14.6.1.0707 ALLOCATE**

```

VARIABLE datasp
HERE datasp !

T{ 50 CELLS ALLOCATE SWAP addr ! -> 0 }T
T{ addr @ ALIGNED -> addr @ }T \ Test address is aligned
T{ HERE -> datasp @ }T \ Check data space pointer is unaffected
addr @ 50 write-cell-mem
addr @ 50 check-cell-mem \ Check we can access the heap
T{ addr @ FREE -> 0 }T

```

## F.16 The optional Search-Order word set

The search order is reset to a known state before the tests can be run.

### ONLY FORTH DEFINITIONS

Define two word list (wid) variables used by the tests.

```

VARIABLE wid1
VARIABLE wid2

```

In order to test the search order it is necessary to remember the existing search order before modifying it. The existing search order is saved and the `get-orderlist` defined to access it.

```

: save-orderlist ( widn ... wid1 n -- )
  DUP , 0 ?DO , LOOP
;

CREATE order-list
T{ GET-ORDER save-orderlist -> }T

: get-orderlist ( -- widn ... wid1 n )
  order-list DUP @ CELLS ( -- ad n )
  OVER + ( -- AD AD' )
  ?DO I @ -1 CELLS +LOOP ( -- )
;

```

Having obtained a copy of the current wordlist, the testing of the wordlist can begin with test [F.16.6.1.1595 FORTH-WORDLIST](#) followed by [F.16.6.1.2197 SET-ORDER](#) which also test `GET-ORDER`, then [F.16.6.2.0715 ALSO](#) and [F.16.6.2.1965 ONLY](#) before moving on to [F.16.6.1.2195 SET-CURRENT](#) which also test `GET-CURRENT` and `WORDLIST`. This should be followed by the test [F.16.6.1.1180 DEFINITIONS](#) which also tests `PREVIOUS` and the [F.16.6.1.2192 SEARCH-WORDLIST](#) and [F.16.6.1.1550 FIND](#) tests. Finally the [F.16.6.2.1985 ORDER](#) test can be performed.

## F.17 The optional String word set

Most of the tests in this wordlist require a known string which is defined as:

```
T{ : s1 S" abcdefghijklmnopqrstuvwxyz" ; -> }T
```

The tests should be carried out in the order: [F.17.6.1.0245](#) /STRING, [F.17.6.1.2191](#) SEARCH, [F.17.6.1.0170](#) -TRAILING, [F.17.6.1.0935](#) COMPARE, [F.17.6.1.0780](#) BLANK and [F.17.6.1.2212](#) SLITERAL.

### F.17.6.1.0170 -TRAILING

```
T{ : s8 S" abc " ; -> }T
T{ : s9 S" " ; -> }T
T{ : s10 S" a " ; -> }T

T{ s1 -TRAILING -> s1 }T \ "abcdefghijklmnopqrstuvwxyz"
T{ s8 -TRAILING -> s8 2 - }T \ "abc "
T{ s7 -TRAILING -> s7 }T \ " "
T{ s9 -TRAILING -> s9 DROP 0 }T \ " "
T{ s10 -TRAILING -> s10 1- }T \ " a "
```

### F.17.6.1.0245 /STRING

```
T{ s1 5 /STRING -> s1 SWAP 5 + SWAP 5 - }T
T{ s1 10 /STRING -4 /STRING -> s1 6 /STRING }T
T{ s1 0 /STRING -> s1 }T
```

### F.17.6.1.0780 BLANK

```
: s13 S" aaaaa a" ; \ Six spaces
T{ PAD 25 CHAR a FILL -> }T \ Fill PAD with 25 'a's
T{ PAD 5 CHARS + 6 BLANK -> }T \ Put 6 spaced from character 5
T{ PAD 12 s13 COMPARE -> 0 }T \ PAD Should now be same as s13
```

### F.17.6.1.0935 COMPARE

```
T{ s1 s1 COMPARE -> 0 }T
T{ s1 PAD SWAP CMOVE -> }T \ Copy s1 to PAD
T{ s1 PAD OVER COMPARE -> 0 }T
T{ s1 PAD 6 COMPARE -> 1 }T
T{ PAD 10 s1 COMPARE -> -1 }T
T{ s1 PAD 0 COMPARE -> 1 }T
T{ PAD 0 s1 COMPARE -> -1 }T
T{ s1 s6 COMPARE -> 1 }T
T{ s6 s1 COMPARE -> -1 }T

: "abdde" S" abdde" ;
: "abbde" S" abbde" ;
: "abcdef" S" abcdf" ;
: "abcdee" S" abcdee" ;

T{ s1 "abdde" COMPARE -> -1 }T
T{ s1 "abbde" COMPARE -> 1 }T
```

```

T{ s1 "abcdf" COMPARE -> -1 }T
T{ s1 "abcdee" COMPARE -> 1 }T

: s11 S" 0abc" ;
: s12 S" 0aBc" ;

T{ s11 s12 COMPARE -> 1 }T
T{ s12 s11 COMPARE -> -1 }T

```

**F.17.6.1.2191 SEARCH**

```

T{ : s2 S" abc" ; -> }T
T{ : s3 S" jklmn" ; -> }T
T{ : s4 S" z" ; -> }T
T{ : s5 S" mnoq" ; -> }T
T{ : s6 S" 12345" ; -> }T
T{ : s7 S" " ; -> }T

T{ s1 s2 SEARCH -> s1 <TRUE> }T
T{ s1 s3 SEARCH -> s1 9 /STRING <TRUE> }T
T{ s1 s4 SEARCH -> s1 25 /STRING <TRUE> }T
T{ s1 s5 SEARCH -> s1 <FALSE> }T
T{ s1 s6 SEARCH -> s1 <FALSE> }T
T{ s1 s7 SEARCH -> s1 <TRUE> }T

```

**F.17.6.1.2212 SLITERAL**

```

T{ : s14 [ s1 ] SLITERAL ; -> }T
T{ s1 s14 COMPARE -> 0 }T
T{ s1 s14 ROT = ROT ROT = -> <TRUE> <FALSE> }T

```

**F.17.6.2.2255 SUBSTITUTE**

30 **CHARS BUFFER:** subbuff \ Destination buffer

\ Define a few string constants

```

: "hi" S" hi" ;
: "wld" S" wld" ;
: "hello" S" hello" ;
: "world" S" world" ;

```

\ Define a few test strings

```

: sub1 S" Start: %hi%,%wld%! :End" ; \ Original string
: sub2 S" Start: hello,world! :End" ; \ First target string
: sub3 S" Start: world,hello! :End" ; \ Second target string

```

\ Define the hi and wld substitutions

```

T{ "hello" "hi" REPLACES -> }T \ Replace "%hi%" with "hello"
T{ "world" "wld" REPLACES -> }T \ Replace "%wld%" with "world"

```

\ "%hi%,%wld%" changed to "hello,world"

```

T{ sub1 subbuff 30 SUBSTITUTE ROT ROT sub2 COMPARE -> 2 0 }T

```

```

\ Change the hi and wld substitutions
T{ "world" "hi" REPLACES -> }T
T{ "hello" "wld" REPLACES -> }T

\ Now "%hi%, %wld%" should be changed to "world,hello"
T{ sub1 subbuff 30 SUBSTITUTE ROT ROT sub3 COMPARE -> 2 0 }T

\ Where the substitution name is not defined
: sub4 S" aaa%bbb%ccc" ;
T{ sub4 subbuff 30 SUBSTITUTE ROT ROT sub4 COMPARE -> 0 0 }T

\ Finally the % character itself
: sub5 S" aaa%%bbb" ;
: sub6 S" aaa%bbb" ;
T{ sub5 subbuff 30 SUBSTITUTE ROT ROT sub6 COMPARE -> 0 0 }T

```

**F.17.6.2.2375 UNESCAPE**

Using subbuff, sub5 and sub6 from [F.17.6.2.2255 SUBSTITUTE](#).

```
T{ sub6 subbuff UNESCAPE sub5 COMPARE -> 0 }T
```

**F.18 The optional Extended Character word set**

These test assume the UTF-8 character encoding is being used.

**F.18.6.1.2487.15 XC!+?**

```
T{ $ffff PAD 4 XC!+? -> PAD 3 + 1 <TRUE> }T
```

**F.18.6.1.2487.25 XC-SIZE**

This test assumes UTF-8 encoding is being used.

**HEX**

```

T{      0 XC-SIZE -> 1 }T
T{     7f XC-SIZE -> 1 }T
T{     80 XC-SIZE -> 2 }T
T{    7ff XC-SIZE -> 2 }T
T{    800 XC-SIZE -> 3 }T
T{   ffff XC-SIZE -> 3 }T
T{  10000 XC-SIZE -> 4 }T
T{ 1ffffff XC-SIZE -> 4 }T

```

**F.18.6.2.2487.30 XC-WIDTH**

```

T{ $606D XC-WIDTH -> 2 }T
T{  $41 XC-WIDTH -> 1 }T
T{ $2060 XC-WIDTH -> 0 }T

```

## Annex G

(informative)

### Change Log

#### 16.1 Bath Meeting (30 September – 2 October, 2015)

– **200x Membership:**

- (1) x:membership: Replaced membership rules.
- (2) ed16: Moved Andrew Haley and Willi Stricker from current to past members.

3 Usage requirements:

- (1) x:2-complement: Removed “Programs that use flags as arithmetic operands have an environmental dependency.” from **3.1.3.1 Flags**.
- (2) x:2-complement: Replaced -32767 with -32768 in **3.1.3.2 Integers**.
- (3) x:2-complement: Removed reference to alternate arithmetic architectures from **3.2.1.1 Internal number representation**.
- (4) x:2-complement: Replaced implementation defined response to overflow/underflow of signed numbers with specific text in **3.2.2.2 Other integer operations**.

4 Documentation requirements:

- (1) x:2-complement: Removed “values returned after arithmetic overflow” from **4.1.1 Implementation-defined options**.

12 Floating-Point Word Set:

- (1) ed16: Replaced 0E with -0E in **12.6.2.1489 FATAN2**.

A Rationale (Annex A):

- (1) x:2-complement: Removed number representations from **A.3.1.2 Character types**.
- (2) ed16: Removed reference to EBCDIC from **A.3.1.2 Character types**.
- (3) x:2-complement: Remove discussion of alternative arithmetic architectures from **A.3.2.1 Numbers**.
- (4) x:2-complement: Revised example in A.3.2.2.2 Other integer operations.
- (5) x:2-complement: Replaced environmental dependency example in **A.5.2.2 Program labeling**.
- (6) x:2-complement: Removed reference to two’s-complement from **A.6.2.2440 WITHIN**.
- (7) x:2-complement: Replaced rational for **A.8.6.1.1140 D>S**.

D Portability guide (Annex D):

- (1) x:2-complement: Removed D.3.2 ALU organization.

E Reference Implementations (Annex E):

(1) x:2-complement: Added [E.6.2.2440](#) WITHIN.

(2) x:2-complement: Added [E.8.6.1.1140](#) D>S.

F Test Suite (Annex F):

(1) x:2-complement: Added test case to [F.6.1.0290](#) 1+.

(2) x:2-complement: Added test case to [F.6.1.1720](#) INVERT.

## 17.1 Konstanz Meeting (7–9 September, 2016)

– Title page:

(1) x:reset: Replaced “ANS X3.215–1994” with “the Forth 2012 standard” in document status.

(2) x:reset: Renamed “The Standardisation Committee” to “The Forth 200x Standardisation Committee” in document status.

– **Foreword:**

(1) x:reset: Revised to refer to Forth 2012 as the starting point for the document.

(2) x:reset: Removed meetings prior to 2015 (Bath) meeting

(3) ed17: Added 2016 (Konstanz) meeting

– **200x Membership:**

(1) ed17: Added Sergey Baranov

(2) ed17: Moved Simon Kaphahn from members list to old members list

(3) ed17: Reinstated Andrew Haley, moving him from the old members list back into the members list

(4) ed17: Added officer title against officer holders

1 Introduction:

(1) ed17: Replaced “2012” with “200x” in title on page 13

3 Usage requirements:

(1) x:1 chars = 1: Replace “at least one” with “exactly one” in [3.1.2 Character types](#)

(2) x:2-complement: Replaced “two’s complement” with “two’s-complement” in [3.2.1.1 Internal number representation](#)

(3) x:2-complement: Replaced “divisions” with “division” in [3.2.2.2 Other integer operations](#)

(4) x:2-complement: Removed “in these case” from [3.2.2.2 Other integer operations](#)

(5) x:2-complement: Added “for operations other than division” to [3.2.2.2 Other integer operations](#)

(6) x:2-complement: Replaced “ $2^{n-1}$ ” with “ $-2^{n-1}$ ” in [3.2.2.2 Other integer operations](#)

(7) x:reset: Removed “X:wordset-query” from [3.2.7 Obsolescent Environmental Queries](#)

(8) x:reset: Removed [3.2.8 Extension queries](#) and table [3.7 Forth 200x Extensions](#)

6–18 All word sets:

x:reset: Removed proposal labels

12 Floating-Point Word Set:

(1) x:to-f-round: Removed [D>F](#) and [S>F](#) conditions from [12.4.1.2 Ambiguous conditions](#)

(2) x:to-f-round: Revised definition of [12.6.1.1130 D>F](#)

(3) x:to-f-round: Revised definition of [12.6.2.2175 S>F](#)

A Rationale (Annex [A](#)):

(1) x:2-complement: Made definition of *n* a clause of previous sentence in [A.3.2.1 Numbers](#)

(2) x:2-complement: Removed “likely” from second paragraph of [A.3.2.1 Numbers](#)

(3) x:2-complement: Removed final paragraph of [A.3.2.1 Numbers](#)

(4) x:2-complement: Remove [A.3.2.2.2 Other integer operations](#)

(5) x:2-complement: Replaced “entitle” with “entitled” in [A.5.2.2 Program labeling](#)

(6) x:2-complement: Replaced “lower” with “lowest” in [A.5.2.2 Program labeling](#)

(7) x:2-complement: Replaced “twos-complement” with “two’s complement” in [A.8.6.1.1140 D>S](#)

E Reference Implementations (Annex [E](#)):

(1) x:2-complement: Added [E.6.1.1910 NEGATE](#)

(2) x:2-complement: Corrected “S>D” to “D>S” in [E.8.6.1.1140 D>S](#)

F Test Suite (Annex [F](#)):

(1) x:1 chars = 1: Added test case to [F.6.1.0897 CHAR+](#)

(2) x:1 chars = 1: Added test case to [F.6.1.0898 CHARS](#)

H Alphabetic list of words (Annex [H](#)):

x:reset: Removed proposal names

## Annex H (informative) Alphabetic list of words

In the following list, the last, four-digit, part of the reference number establishes a sequence corresponding to the alphabetic ordering of all standard words. The first two or three parts indicate the word set and glossary section in which the word is defined.
